## **Decay Spectroscopy of Neutron-Rich Cd Around the** N = 82 **Shell Closure (student talk)**

Friday, 16 February 2018 11:00 (15 minutes)

The neutron-rich Cadmium isotopes around the well-known magic numbers at Z = 50 and N = 82 are prime candidates to study the evolving shell structure observed in exotic nuclei. Additionally, the extra binding energy observed around the nearby doubly-magic <sup>132</sup>Sn has direct correlations in astrophysical models, leading to the second r-process abundance peak at  $A \approx 130$  and the corresponding waiting-point nuclei around N = 82. The  $\beta$ -decay of the N = 82 isotope <sup>130</sup>Cd into <sup>130</sup>In was first studied a decade ago [1], but the information for states of the lighter indium isotope (<sup>128</sup>In) is still limited. Detailed  $\beta\gamma$ -spectroscopy of <sup>128</sup>Cd was accomplished using the GRIFFIN [2] facility at TRIUMF, which is capable of performing spectroscopy down to rates of 0.1 pps.

The ongoing analysis of the <sup>128,131,132</sup>Cd will be presented. Already in

<sup>128</sup>Cd, 23 new transitions and 15 new states have been observed in addition to the 4 previously observed excited states [3]. These new results are compared with recent Shell Model calculations. For <sup>131</sup>Cd, results will be compared with the recent EURICA data. These data highlight the unique capabilities of GRIFFIN for decay spectroscopy on the most exotic, short-lived isotopes, and the necessity to re-investigate even "well-known" decay schemes for missing transitions.
