The Dark Matter Question

So far, evidence for existence of DM comes from astrophysics
How to look for it in particle physics experiments?

The Idea of Dark Matter Started in Astrophysics

The Early History of Dark Matter

SIDNEY VAN DEN BERGH

The discovery by Zwicky (1933) that visible matter accounts for only a tiny fraction of all of the mass in the universe may turn out to have been one of the most profound new insights produced by scientific exploration during the 20th century. From observations of the radial velocities of eight galaxies in the Coma Cluster, Zwicky found an unexpectedly large velocity dispersion,

... Zwicky concluded from these observations that, for a velocity dispersion of 1000 km s^{-1} , the mean density of the Coma Cluster would have to be 400 times greater than that which is derived from luminous matter. Zwicky overestimated the mass-to-light ratio

... His value for the overdensity of the Coma Cluster should therefore be reduced from 400 to ~ 50 .¹ Zwicky writes (my translation): "If this [overdensity] is confirmed we would arrive at the astonishing conclusion that dark matter is present [in Coma] with a much greater density than luminous matter." He continues: "From these considerations it follows that the large velocity dispersion in Coma (and in other clusters of galaxies) represents an unsolved problem."

Fritz Zwicky estimated total mass of a galaxy cluster via two different methods:

1. Observed brightness
2. Virial theorem (using velocities of the bodies)

After a mismatch between the results, Zwicky proposed another method to settle the disagreement:

3. Gravitational lensing

Zwicky hypothesized non-luminous "dark matter", but in the form of previously-overlooked gas, dust, and very faint dwarf stars for which he spent ~ 20 years looking!

Cosmic Microwave Background

Galactic Rotation Curves

Large-Scale Structure

Collisions between galaxy clusters

Galaxy Cluster Collisions

Once upon a time, at the far end of the universe, two galaxy clusters collided. Their head-on encounter tore apart the galaxies and left behind two reconfigured heaps of stars and gas, separating again and moving apart from each other, destiny unknown.

...

In the below image of the Bullet Cluster you see three types of data overlaid. First, there are the stars and galaxies in the optical regime. (Can you spot the two foreground objects?) Then there are the regions colored red which show the distribution of hot gas, inferred from X-ray measurements. And the blue-colored regions show the space-time curvature, inferred from gravitational lensing which deforms the shape of galaxies behind the cluster.

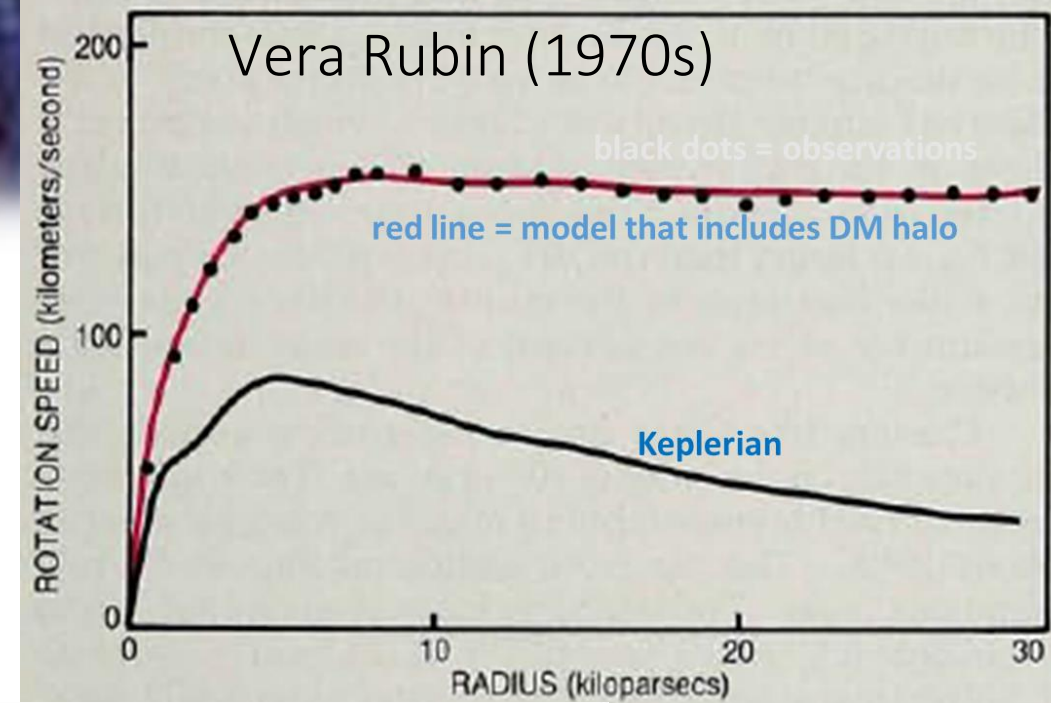

- Sabine Hossenfelder, BackRe(action)

Explanation requires feebly-interacting non-luminous matter, or modified gravity

Galactic rotation curves

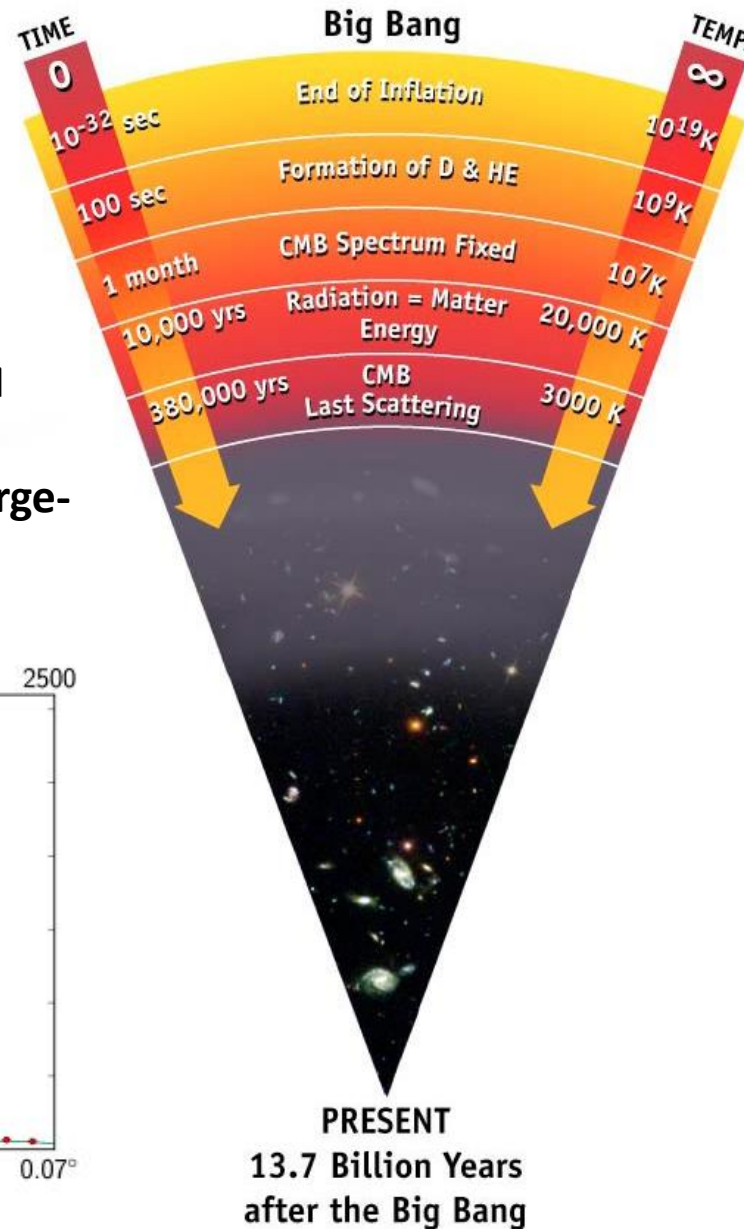

- **Rotation curve:** for stars in a galaxy, plot of stellar circular speed v_c as a function of radial distance from galactic centre R
- “Keplerian behaviour”: predicted by Kepler’s (Newton’s) classical laws of gravity & motion, based on the mass of observed visible matter
- *Rubin calculated gravitational field from the disk is too small by a factor of ~ 10 to account for the observed rotation*

CMB

Anisotropy ($< 1/10,000$) indicates very small fluctuations at CMB emission time, when SM matter started clustering ...

How could these clusters have turned into large-scale structures in the time since then?

We can only see the surface of the cloud where light was last scattered

PRESENT
13.7 Billion Years
after the Big Bang

The cosmic microwave background Radiation's "surface of last scatter" is analogous to the light coming through the clouds to our eye on a cloudy day.

<https://map.gsfc.nasa.gov/media/990053/index.html>

<https://sci.esa.int/web/planck/-/51555-planck-power-spectrum-of-temperature-fluctuations-in-the-cosmic-microwave-background>

Large-scale structure formation

DM model must give correct degree of large-scale structure formation (right amount of clumping) when we compare cosmological simulations to observations from sky surveys

time

Early universe
(more diffuse)

Note: universe is expanding, so each “box” is also growing in size, much more than can be shown

Present-day
(more clustered)

Simulation Images: Andrey Kravtsov & Anatoly Klypin, National Center for Supercomputer Applications

Other Astrophysical Constraints on DM

- Prior to CMB was “Big Bang nucleosynthesis”, when H and He were formed
 - Extra baryonic matter upsets H : He ratio, providing evidence DM is non-baryonic
- Then came star formation
 - DM accreting in stellar cores must not cause stars to collapse too much, prevent stars from igniting, nor prevent supernovas from exploding

DM Candidates

Targeting “Beyond the Standard Model” Searches

DM searches → looking for BSM particle(s)
with the following properties:

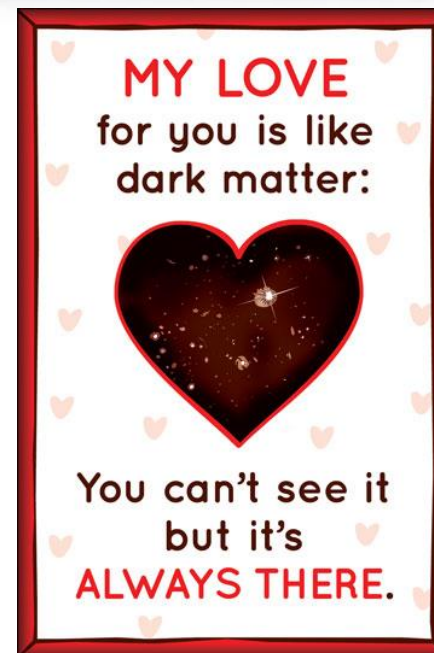

- Cold (non-relativistic)
- Stable on cosmological timescales
- Gravitationally interacting
- Feeble, if any, non-gravitational self-interactions
- Feeble, if any, non-gravitational interactions with luminous matter

What mass scale?

What interactions with SM?

Are there “dark forces”?

How many new particle species?

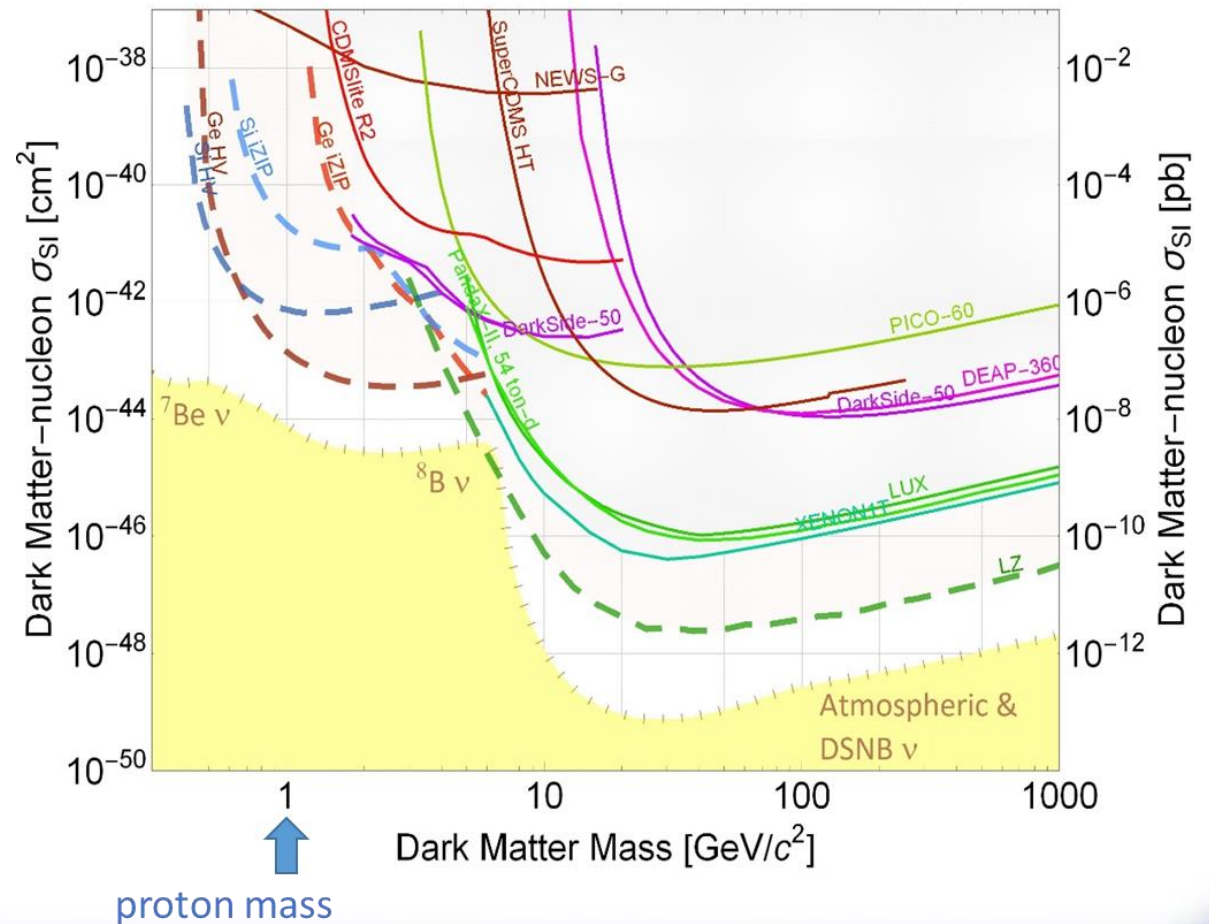

WIMPing out?

“Weakly Interacting Massive Particles” (WIMP) candidates:

- Supersymmetric partners
- Additional Higgs bosons
- “Mirror universe” / “Hidden Valley” particles
- Kaluza-Klein particles
- Sterile neutrinos
- ... etc

But... searches *where we most expected to find WIMPs* haven't found them!

Particle Zoo!

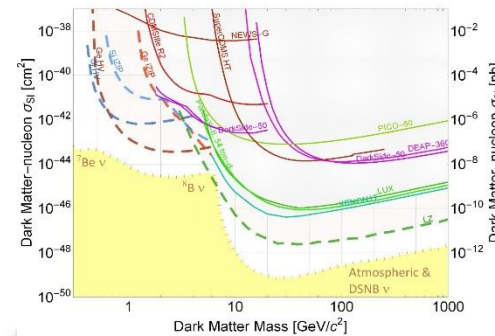

“Zoo” of possibilities

Non-WIMP candidates

- FIMPs (Feebly Interacting), WIMPzillas (> 1000 TeV), SIMPs (Self-Interacting), ELDERs (Elastically Decoupling Relics), ...
- Low-mass dark photons (sub-GeV)
- Lightly-ionizing / millicharged particles (sub-GeV)
- Axion-like particles (sub-eV)
- Massive gravitons
- Particles with only gravitational interactions and/or self-interactions
- MACHOs (Massive Compact Halo Objects), e.g. primordial black holes
- Modified [quantum / super-] gravity

Lower-mass Thermal Relics?

- Thermal relic dark matter works fine (theoretically) at least down to $2m_e$
- But “light WIMP-like DM” requires new, comparably low-mass “dark mediators” (dark force carriers, e.g. dark photons)
- Experimental challenges: look for the mediators, as well as sub-GeV DM?

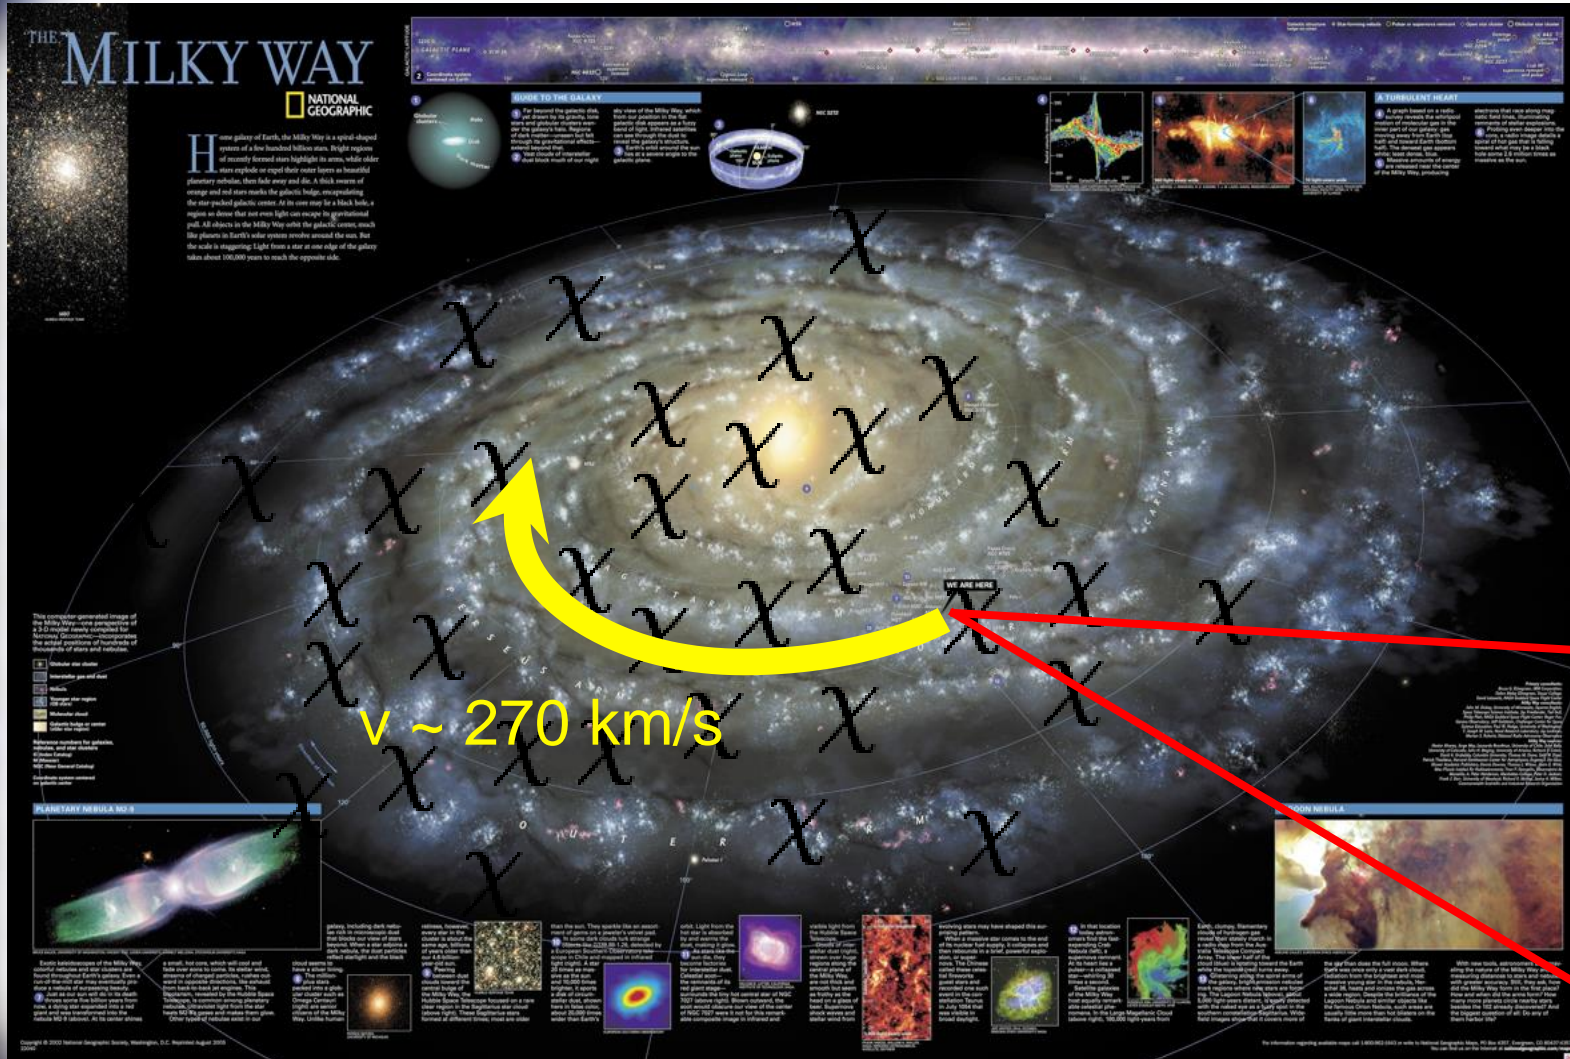

Search Strategies

Search Strategies

Complementarity between different types of experiments

Direct Detection

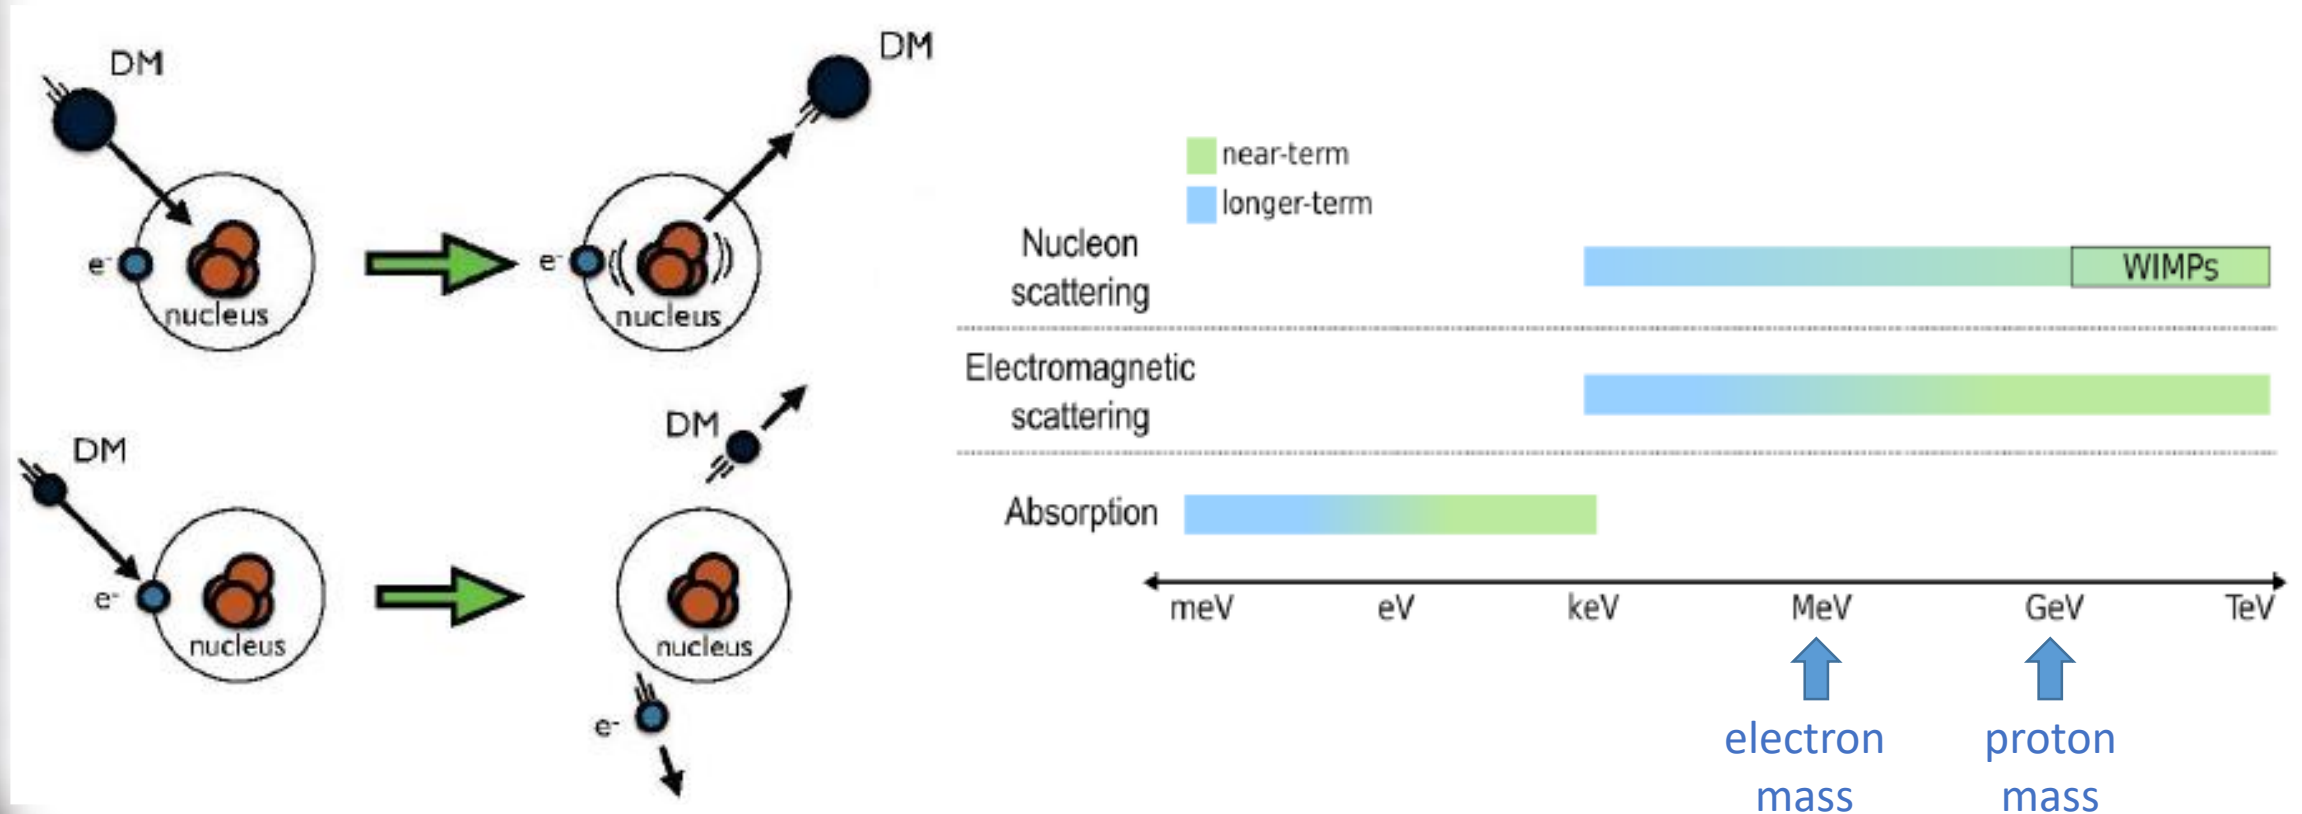

Collisions of galactic DM with SM particles in detector on Earth

Direct Detection

DM particles collide with SM particles in detector “target” and are absorbed, or cause nuclear and/or electronic recoils

Direct Detection

particle theory nuclear structure local properties of DM halo

$$\frac{dR}{dE_R} = \frac{\sigma_o}{m_\chi} \frac{F^2(E_R)}{m_r^2} \frac{\rho_o T(E_R)}{v_o \sqrt{\pi}}$$

recoil energy of nucleus

$m_r = \frac{m_\chi m_N}{m_\chi + m_N}$

reduced mass of DM-nucleon system

Local $\rho_{\text{DM}} \approx 0.4 \text{ GeV/cm}^3$
 $v_{\text{DM}} \approx 220 \text{ km/s}$ (non-relativistic)

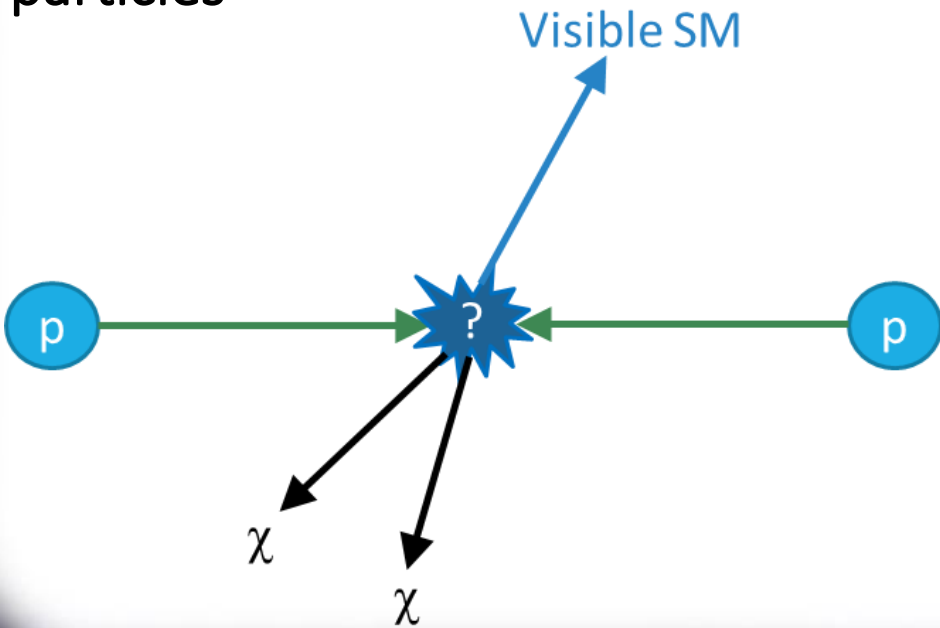

For $m_{\text{DM}} \approx 1 \text{ GeV}$:
 $\text{flux}_{\text{DM}} \approx 10 \text{ million / cm}^2\text{s}$

Collider Searches

Most recent at Large Hadron Collider

Often look for “missing transverse energy” carried off by DM produced in association with visible SM particles

ATLAS SUSY Searches* - 95% CL Lower Limits

*Only a selection of the available mass limits on new states or phenomena is shown. Many of the limits are based on simplified models, c.f. refs. for the assumptions made.

Fixed-Target Searches

When particle beam collides with fixed target, DM produced in association with visible SM particles

Only the DM reaches detector behind "beam dump" and dirt

Indirect Detection

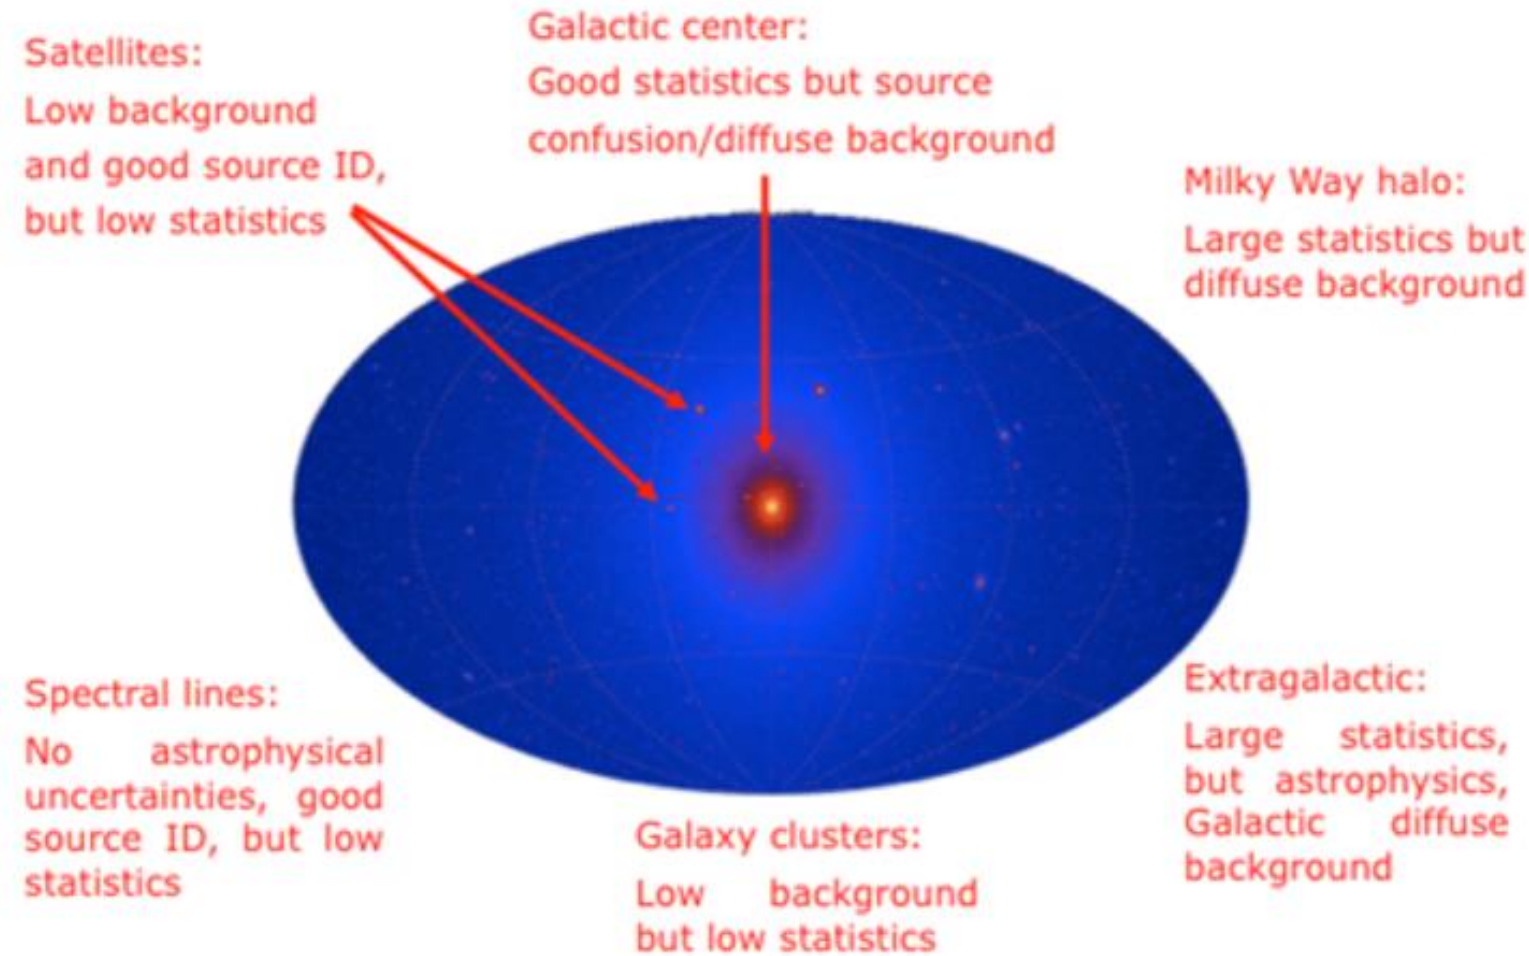

Collisions of WIMPs in outer space could produce SM particles that travel to Earth

“Signals” (e.g. excess photons of a certain frequency) detected by ground- or space-based telescopes

Indirect Detection

Expect some cosmic neighborhoods to have more DM than others

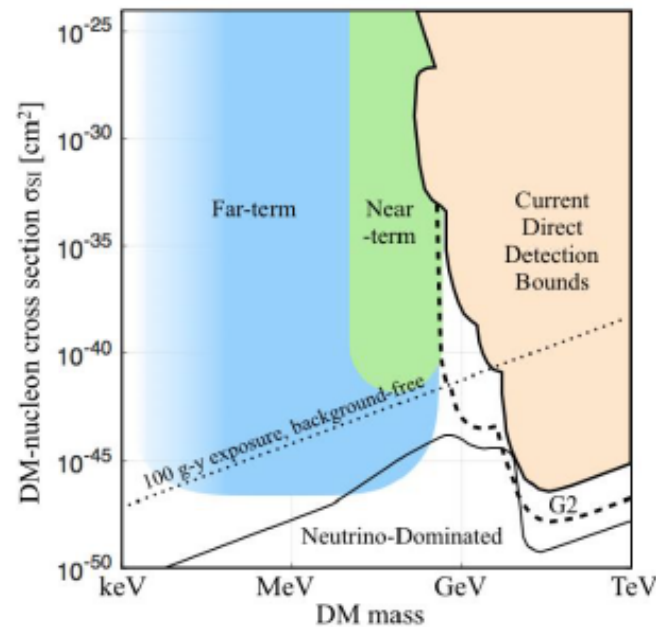

But some also give off more backgrounds

Direct Detection Experiments

Moment of Truth

Next few years will either *find conventional WIMPs* or *rule them out*.

Lowering *mass* and/or *interaction* thresholds mean tougher backgrounds, and we will encounter “floor” where neutrinos drown out WIMP signal

Galactic dark matter scattering off nuclei

Galactic dark matter scattering off electrons

Galactic dark-photons absorbed by electrons

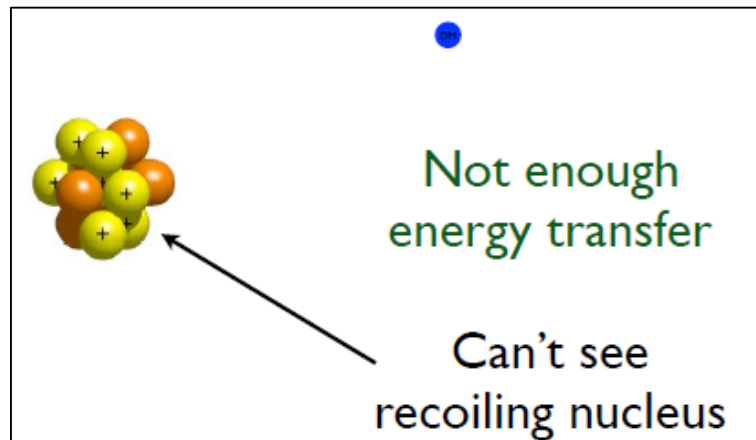

Next-Generation Direct Detection

The Sub-GeV Detection Challenge

- Can rely on elastic NR signal for DM masses down to \sim a few GeV
- But not for sub-GeV DM: inefficient momentum & energy transfer
- Alternatives: inelastic processes, electron recoils

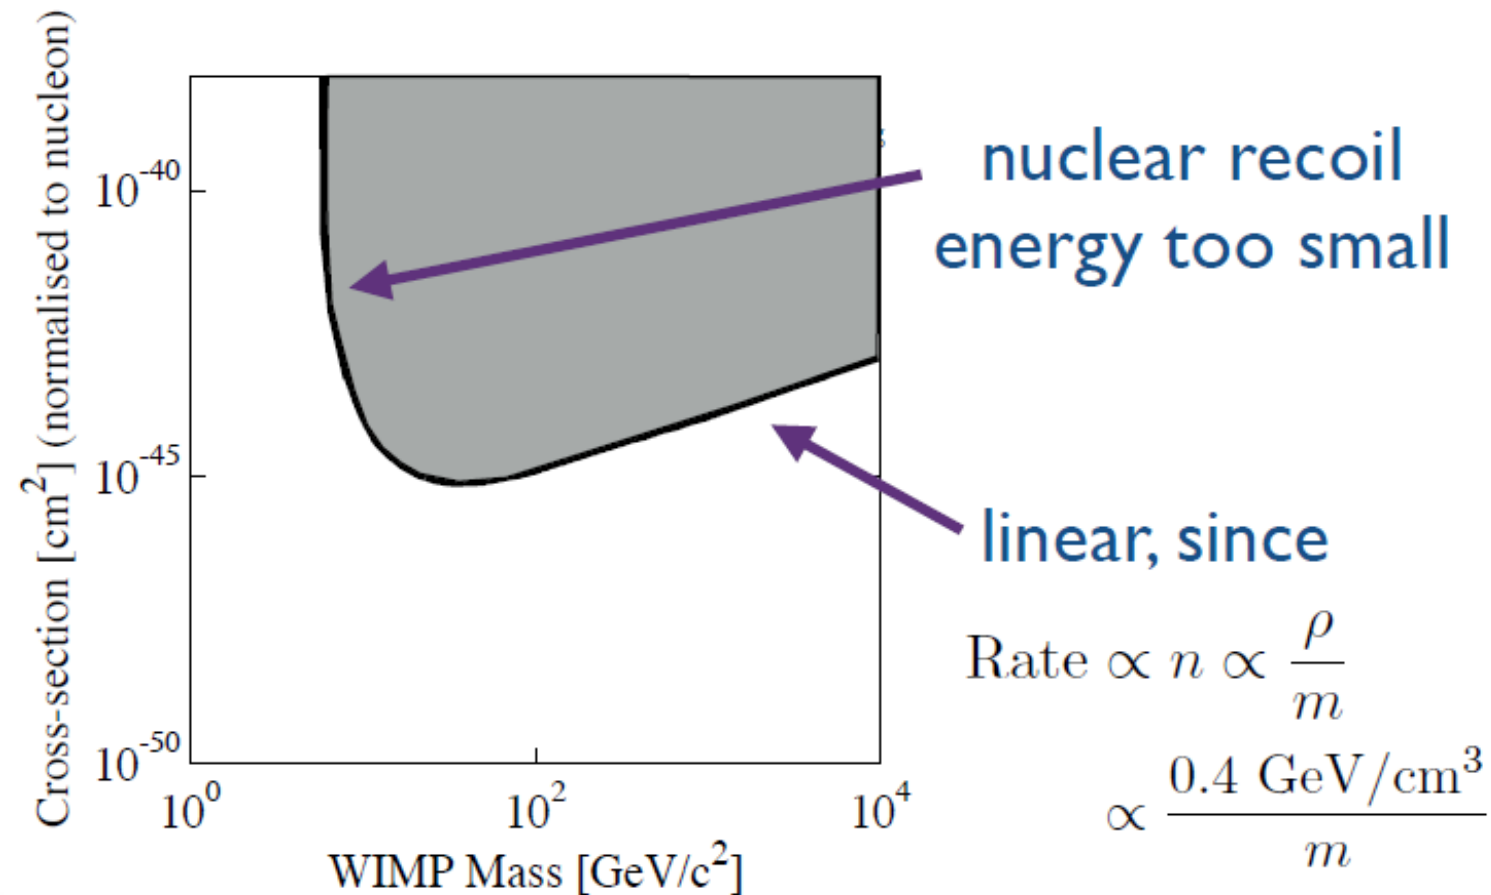

$$E_{\text{NR}} = \frac{q^2}{2m_N} \leq \frac{2\mu_{\chi N}^2 v_\chi^2}{m_N} \simeq \frac{2m_\chi^2 v_\chi^2}{m_N}$$

R. Essig

Search Status

Schematic view of typical direct-detection limit curve:

Various Options for ER & Dark Absorption

- Detectable electron recoil energies and DM masses:

noble liquids

$$\Delta E \sim 10 \text{ eV}$$

$$m_{\text{DM}} \sim 5 \text{ MeV}$$

semiconductors
scintillators

$$\Delta E \sim 1 \text{ eV}$$

$$m_{\text{DM}} \sim 500 \text{ keV}$$

superconductors
(R&D)

$$\Delta E \sim \text{few meV}$$

$$m_{\text{DM}} \sim \text{keV}$$

Dirac materials
(speculative "exotic")

...

Next-Generation Direct Detection

Bubble Chambers

- Jar of superheated liquid
- Incoming particle deposits energy, causing bubbles to nucleate
- Minimum deposition required to overcome surface tension: a few keV
- Cameras and/or acoustic sensors trigger on bubbles, then re-set chamber by pressurizing it
- e.g. PICO

Bubble Chambers

Noble Liquid/Gas Detectors

- Large tank of liquid noble element (xenon or argon) attached to sensors for light and ionization energy of particle interactions
- May also have gaseous layer
- Shielded, and often underground, to avoid interference from cosmic rays and ambient radiation
- e.g. XENON, LUX, LZ, PandaX, DarkSide, DEAP

Noble Liquid/Gas Detectors

arXiv: 1512.03506

Many Next-Generation Detectors are Solid-State

Low thresholds on phonon channels: not subject to quenching effects that reduce ionization & scintillation signals at low energy

Phonon signal independent of particle interaction type, while ionization / scintillation can provide ER vs NR discrimination

<https://arxiv.org/abs/1509.08767>

Cryogenic Semiconductor Crystals

- Trigger & analysis thresholds tens of eV
- Tens of mK
- Tens of grams

SuperCDMS

<https://arxiv.org/abs/1509.08767>

- Shielding (lead, copper, polyethylene)
- Radiopure environment

Cryogenic Semiconductor Crystals

**EDELWEISS (Expérience pour Detecter Les WIMPs En Site Souterrain):
neutron-transmutation-doped Ge**

**-III FD800 at Modane Underground
Laboratory: combination of
phonon and ionization channels
allows NR vs ER discrimination**

**-SURF at Institut de Physique
Nucleaire de Lyon surface facility:
phonon channel only**

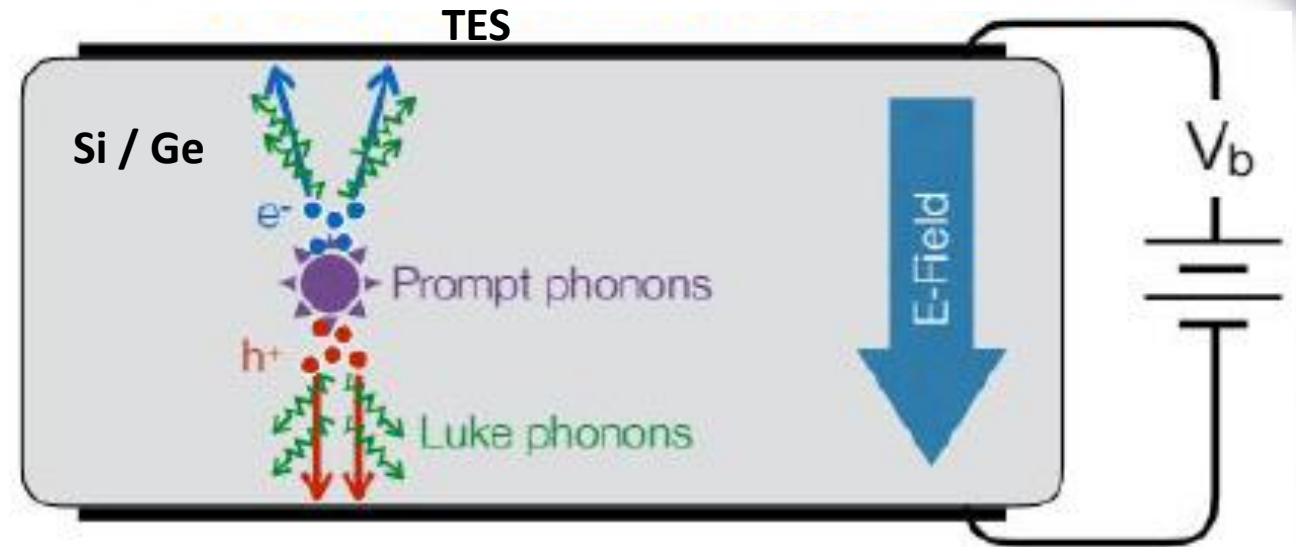

<https://arxiv.org/abs/1706.01070>

Cryogenic Semiconductor Crystals

SuperCDMS (Cryogenic Dark Matter Search) Soudan / SNOLAB:

- Ge and Si crystals
- E_t measured using transition edge sensors (TESs) read out by SQUIDs
- n_{eh} measured using high electron mobility transistors (“iZIP” detectors)
- Drifting charges across a V_b generates Luke phonons (“HV” detectors)
 - Lowers recoil energy threshold
 - But “true calorimetry” and NR vs ER discrimination lost

$$E_t = E_r + n_{eh}qV_b$$

Total phonon energy Primary recoil energy Luke phonon energy

Cryogenic Semiconductor Crystals

- SuperCDMS “HVeV”, “CPD” Si prototypes:
 - Gram-scale devices
 - Single electron-hole pair resolution
 - Few eV baseline phonon resolution
 - In runs at SLAC and Northwestern surface test facilities so far, just day(s) of live-time yielded near-world-leading DM limits

<https://arxiv.org/abs/2005.14067>

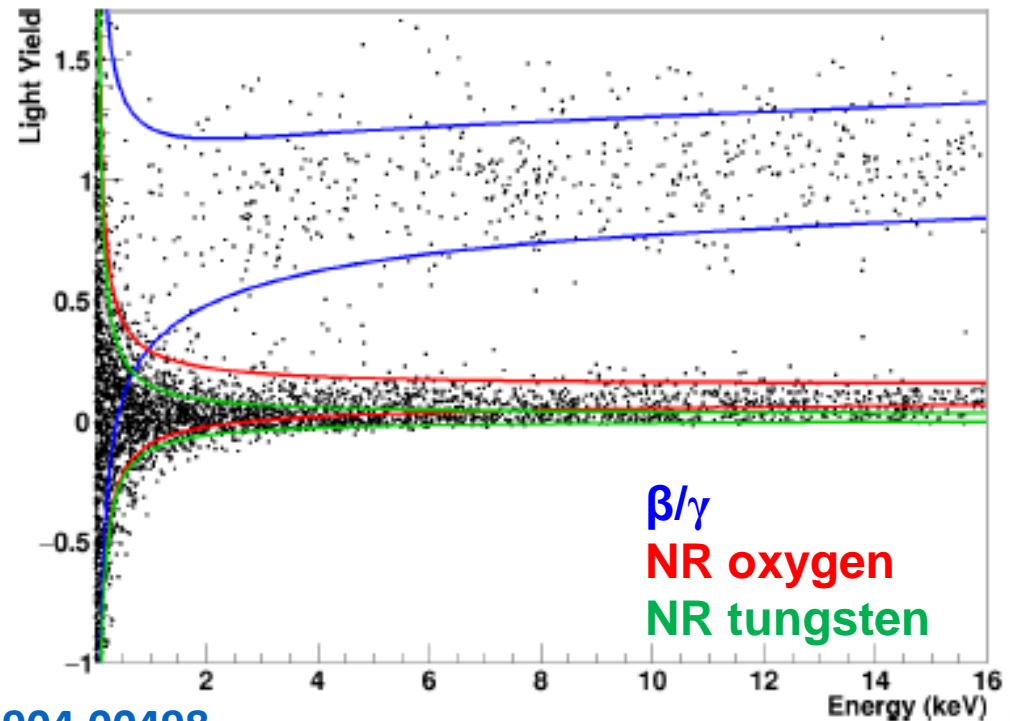

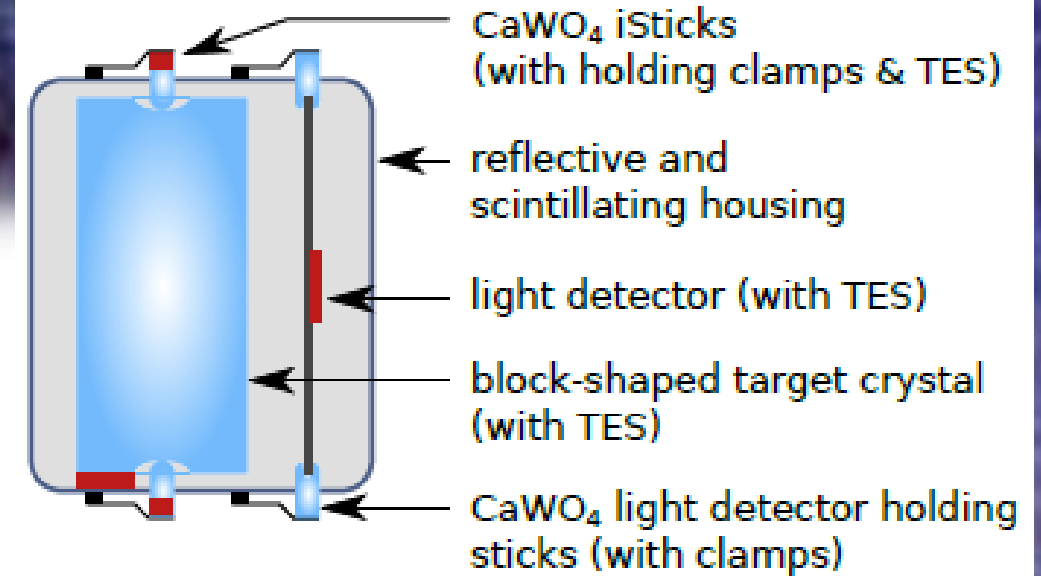

<https://arxiv.org/abs/2007.14289>

Cryogenic Scintillating Crystals

CRESST-III (Cryogenic Rare Event Search with Superconducting Thermometers) at Laboratori Nazionali del Gran Sasso: CaWO_4

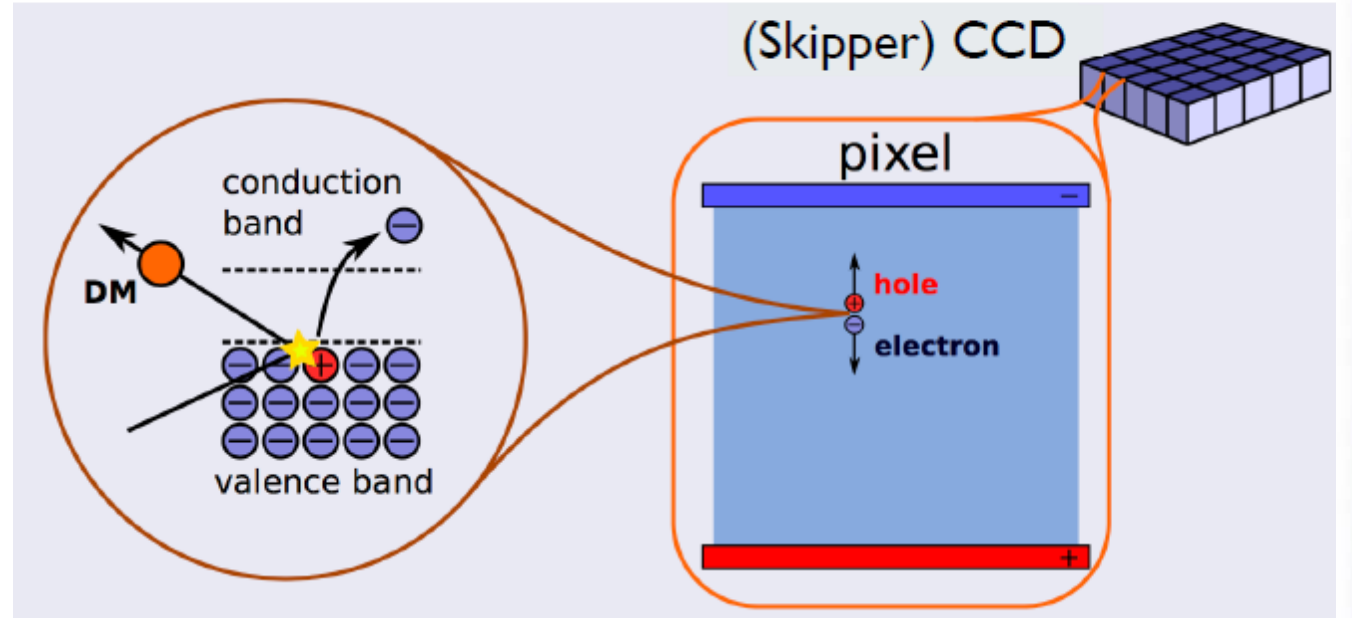

- TESs read out by SQUIDs
- Scintillation light emitted simultaneously with primary phonon signal
 - Collected in separate light absorber (e.g. silicon-on-sapphire)
 - Light yield ($E_{\text{light}}/E_{\text{phonon}}$) provides ER vs NR discrimination
- ~5 mK
- Active muon veto

<https://arxiv.org/abs/1904.00498>

Charge-Coupled Devices

- Ionization events induced in bulk Si of CCDs
- Underground in light-tight housing
- 1 or 2 electron resolution
- ~130-140 K

DM would create one or a few electrons in a pixel

R. Essig

Charge-Coupled Devices

DAMIC (Dark Matter In CCDs) at SNOLAB: thick, fully depleted CCDs with applied drift field

- 7 CCDs: each 6.0 g, 4k x 4k-pixels, $15 \times 15 \mu\text{m}^2$ pixel size, 675 μm thick
- Very low leakage current
- Operated in vacuum, with shielding
- “Image” formed by several hours of exposure followed by serial readout

<https://arxiv.org/abs/1907.12628>

Charge-Coupled Devices

SENSEI (Sub-Electron-Noise Skipper-CCD Experimental Instrument) at Fermilab:

- “Skipper” readout measures each pixel 800x
- Prototype: each quadrant ~ 0.025 g, 624 x 362 pixels, $15 \times 15 \mu\text{m}^2$ pixel size, 200 μm thick
- Continuous readout mode: ~ 1 hr exposure time per pixel (given by Skipper-CCD readout time)
- Periodic mode: several hours exposure followed by readout of all pixels

<https://arxiv.org/abs/1901.10478>

Shedding Light on Low-Energy Backgrounds

- Low-energy background events, of unknown origin, observed in:
 - XENON1T, DarkSide-50 (liquid nobles)
 - SENSEI, DAMIC, SuperCDMS, EDELWEISS, CRESST-III (solid-state)
- Possible explanations in solid-state detectors include:
 - Cherenkov radiation
 - Transition radiation
 - Cracking/micro-fracturing of crystals or holders
 - Luminescence & phonons from recombination

<https://arxiv.org/abs/2011.13939>
