## Design of the Beam Transport Optics of TRIUMF's New $300~{\rm keV~H^-}$ Ion Source

Type: Poster (by default)

The ion source and injection system beamline is used to transport the  $300\,\mathrm{keV}$  H $^-$  beam from the ion source to the injection point of the  $500\,\mathrm{MeV}$  cyclotron at TRIUMF. A new ion beam transport system has been designed to transport a highly intense and bright beam extracted from the H $^-$  ion source. This new system will be installed at the new injection terminal for TRIUMF's  $500\,\mathrm{MeV}$  cyclotron. The low energy part of the transport section ( $25\,\mathrm{keV}$ ) in the injection terminal has been designed with magnetic optical elements in order to maintain space-charge neutralization. The injection terminal includes a permanent magnet solenoid lens, magnetic steerers, a pulser, a beam dump, and a  $300\,\mathrm{kV}$  accelerator column with electron and positive ion suppressor rings. Beam optics calculations have been performed, including space-charge effects up to 1 mA. The simulation results of the beam optics design and the initial beam emittance measurements for the prototype beam transport system will be presented.
