# Model bias

Hits:  $P(\theta) = \prod_{i=1}^N p_i^{\theta_i} (1-p_i)^{1-\theta_i}$

BCE:  $\theta_i \ln p_i + (1-\theta_i) \ln(1-p_i)$

$p_i = \sigma(\hat{\theta}_i)$

$\mathcal{L} = \text{MSE}(x, \hat{x}) + \text{BCE}(\hat{\theta}, \theta(x)) + \text{KL-Div}$

ID	x	L	$\hat{\theta}$
1	1	1	0
2	100	100	0
3	0	0	0

Error from ID 2 is 100 times larger than error from ID 1

But BCE in its current form doesn't take that into consideration

⇒ ADD Weights  $\propto f(x)$

# Model bias

$$\mathcal{L} = \text{MSE}(x, \hat{x}) + \text{BCE}(\hat{\Theta}, \Theta(x)) + \text{KL-Div}$$

$$\text{MSE}(x, \hat{x}) = (x - \hat{x})^2$$

$$\nabla_{\Omega} \text{MSE}(x, \hat{x}) = 2(x - \hat{x}) \cdot \hat{\Theta} \frac{\partial \hat{x}}{\partial \Omega}$$

ID	x	z	Θ-hat
1	1	2	0
2	100	1	0
3	0	0	0
4	0	100	1

$$\nabla_{\Omega} \text{MSE}$$

$$2(1-2) \cdot 0 \cdot \frac{\partial \hat{x}}{\partial \Omega} = 0$$

$$2(100-1) \cdot 0 \cdot \frac{\partial \hat{x}}{\partial \Omega} = 0$$

$$2(0-100) \cdot 1 \cdot \frac{\partial \hat{x}}{\partial \Omega} \neq 0$$

Θ(x)	Θ-hat	Effect on MSE
1	0	Null
0	1	force activation to zero

# Model bias

$$\mathcal{L} = \text{MSE}(x, \hat{x}) + \text{BCE}(\hat{\theta}, \Theta(x)) + \text{KL-Div}$$

$$\text{MSE}(x, \hat{x}) = (x - \hat{x})^2$$

$$\nabla_{\hat{\theta}} \text{MSE}(x, \hat{x}) = 2(x - \hat{x}) \cdot \hat{\theta} \frac{\partial \hat{x}}{\partial \hat{\theta}}$$

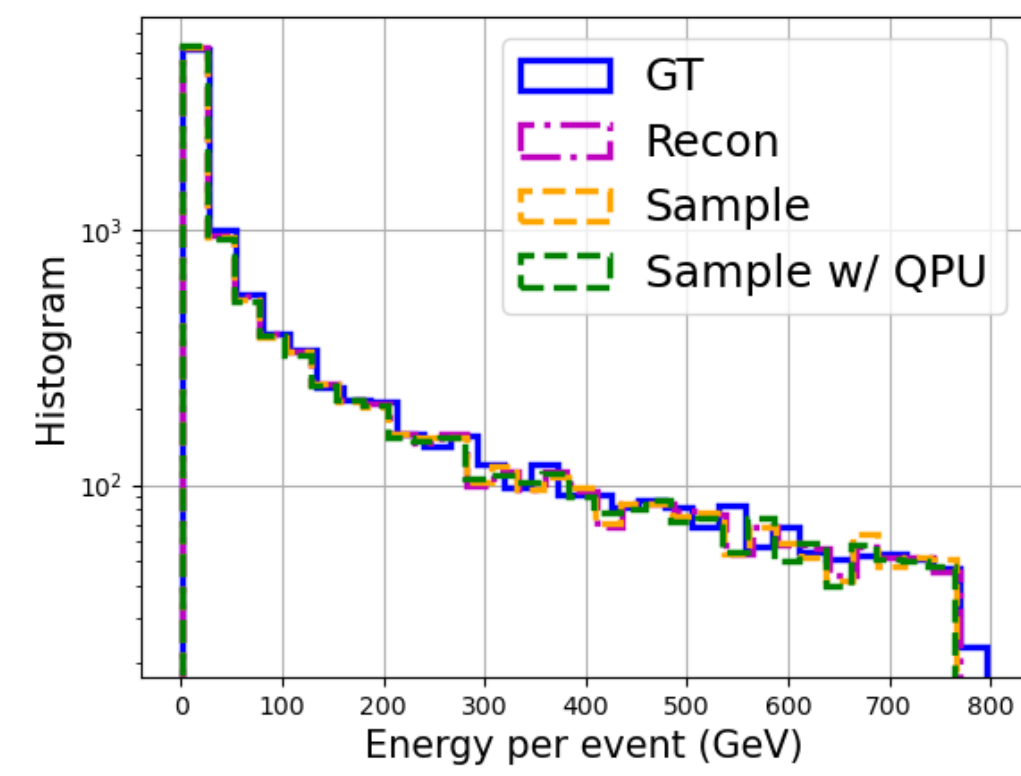

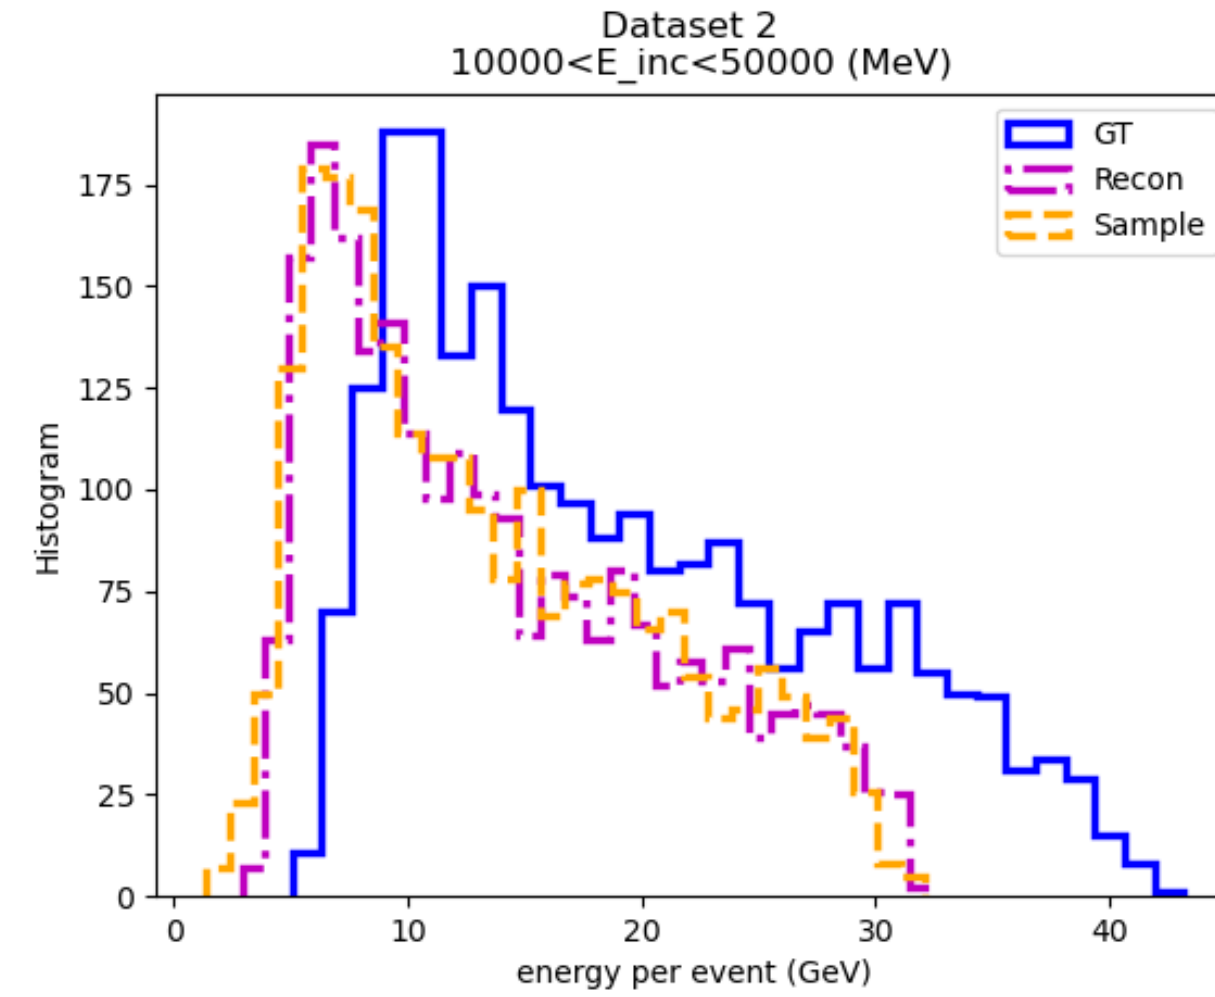

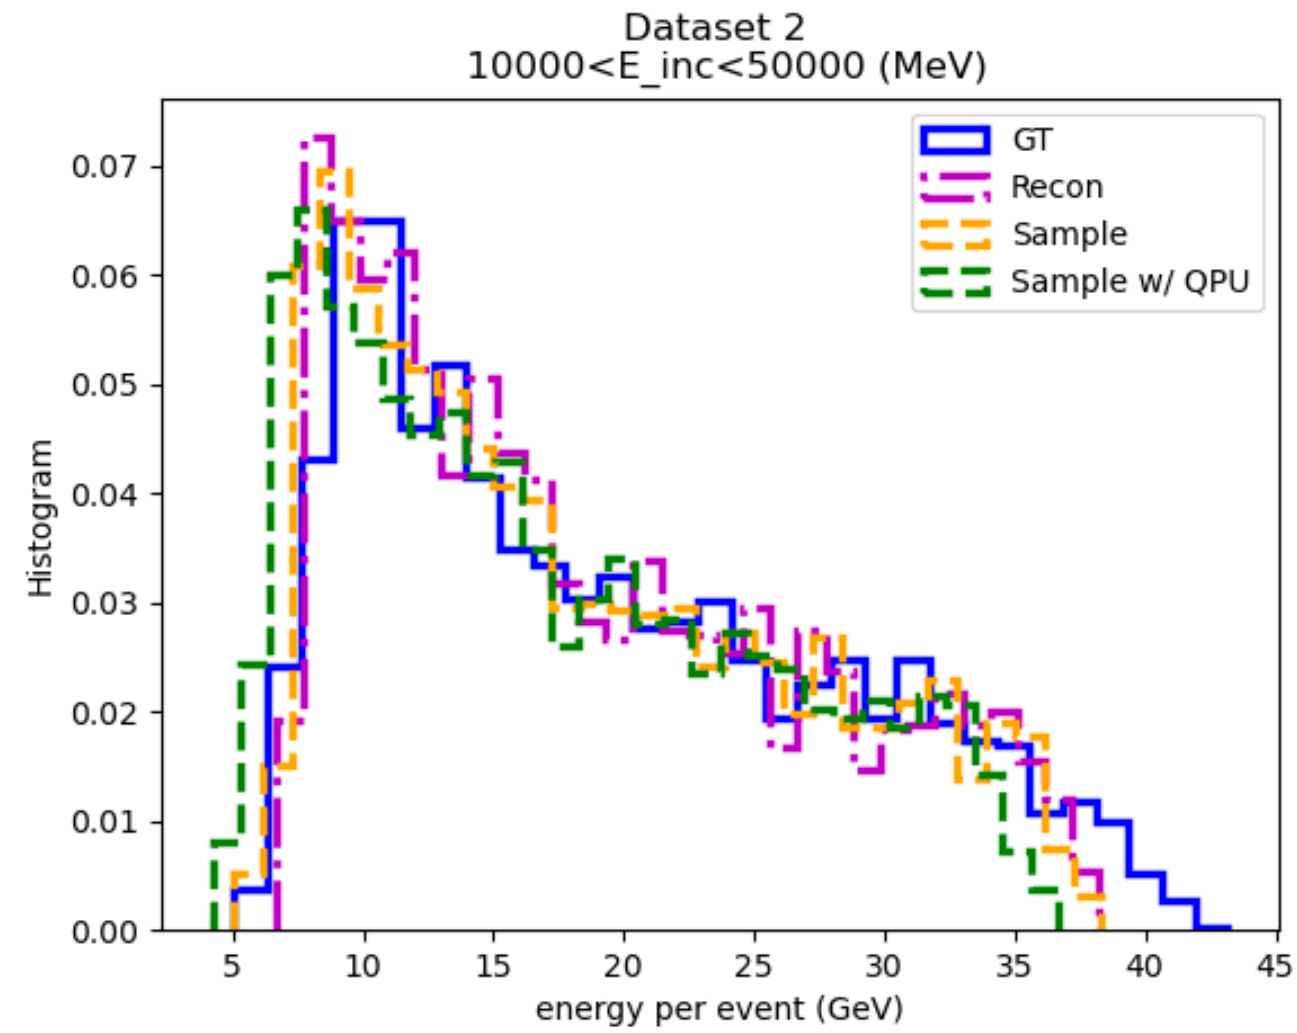

Solution: During training:  $\hat{x} = \zeta \otimes \Theta(x)$

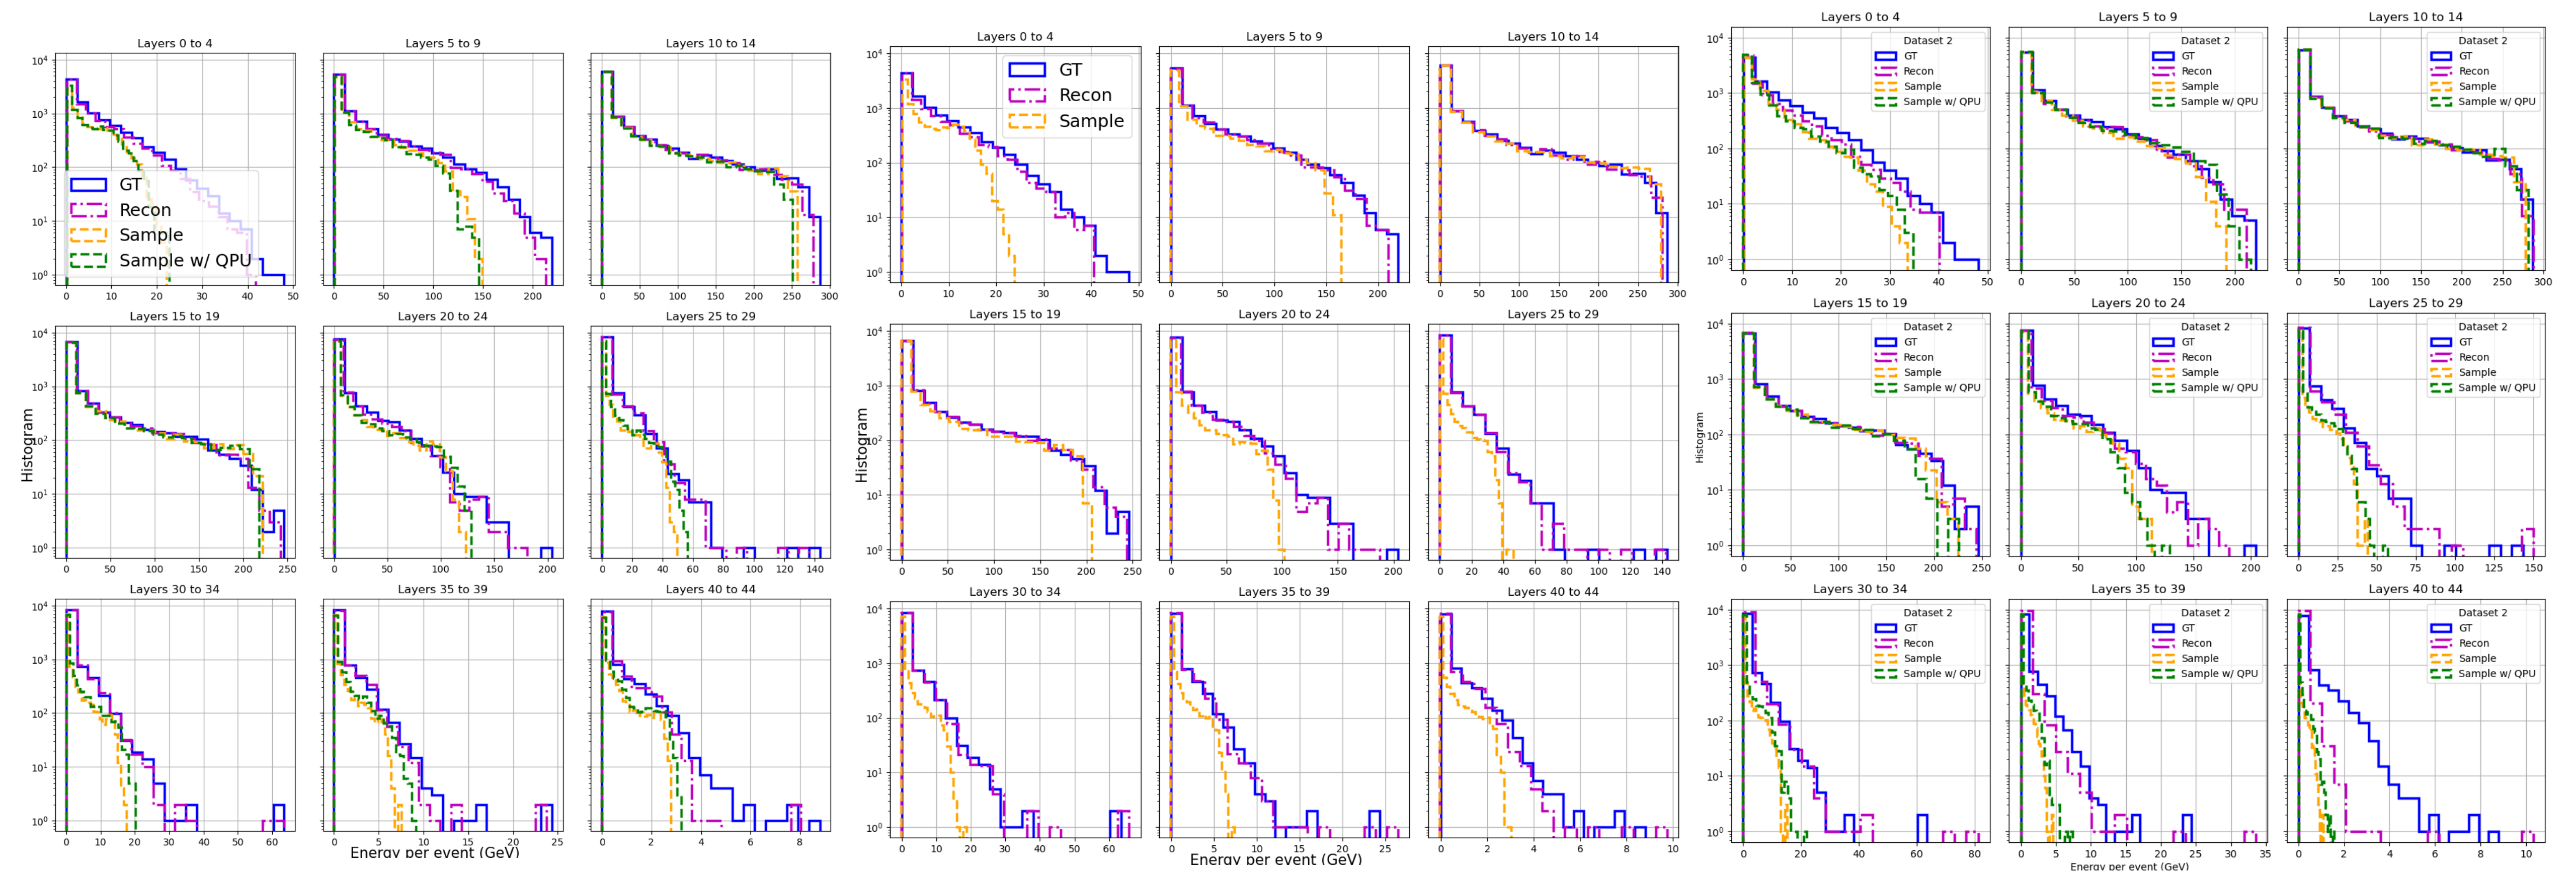

During testing:  $\hat{x} = \zeta \otimes \hat{\theta}$

$\Theta(x)$	$\hat{\theta}$	Effect on MSE
1	0	Null
0	1	force activation to zero

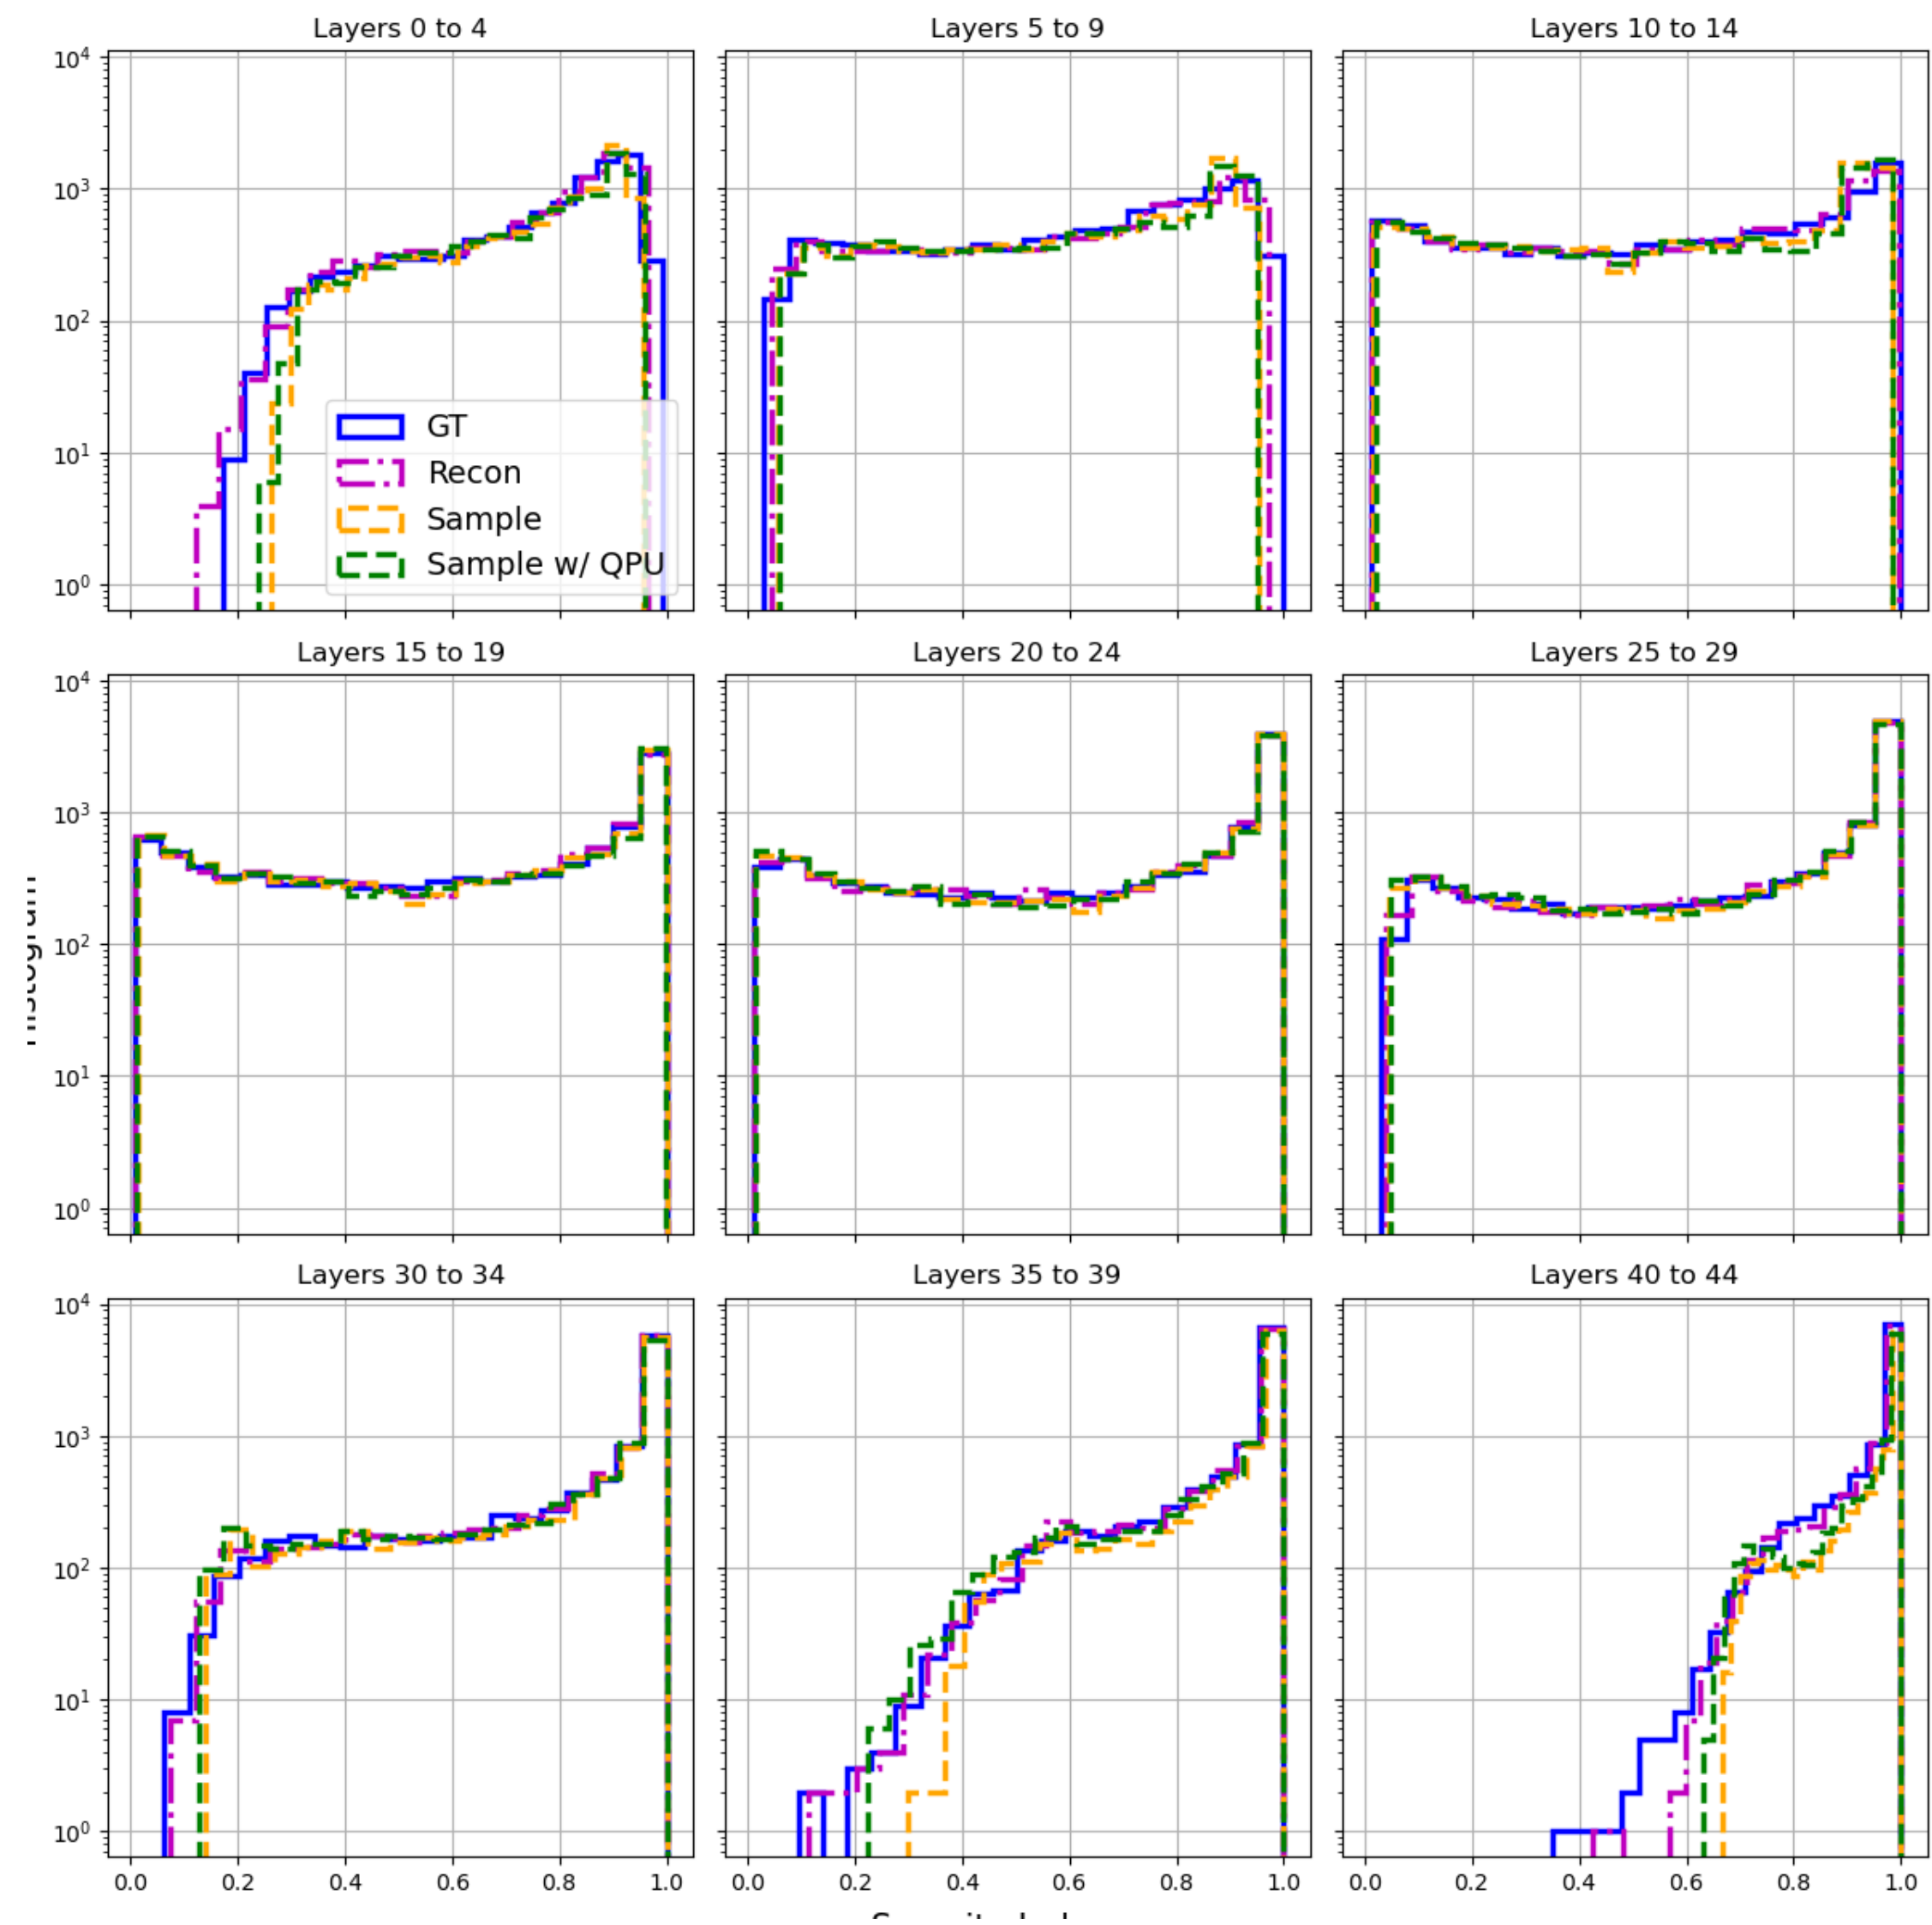

This effectively biases the model towards low energies! (which would explain the undershooting)

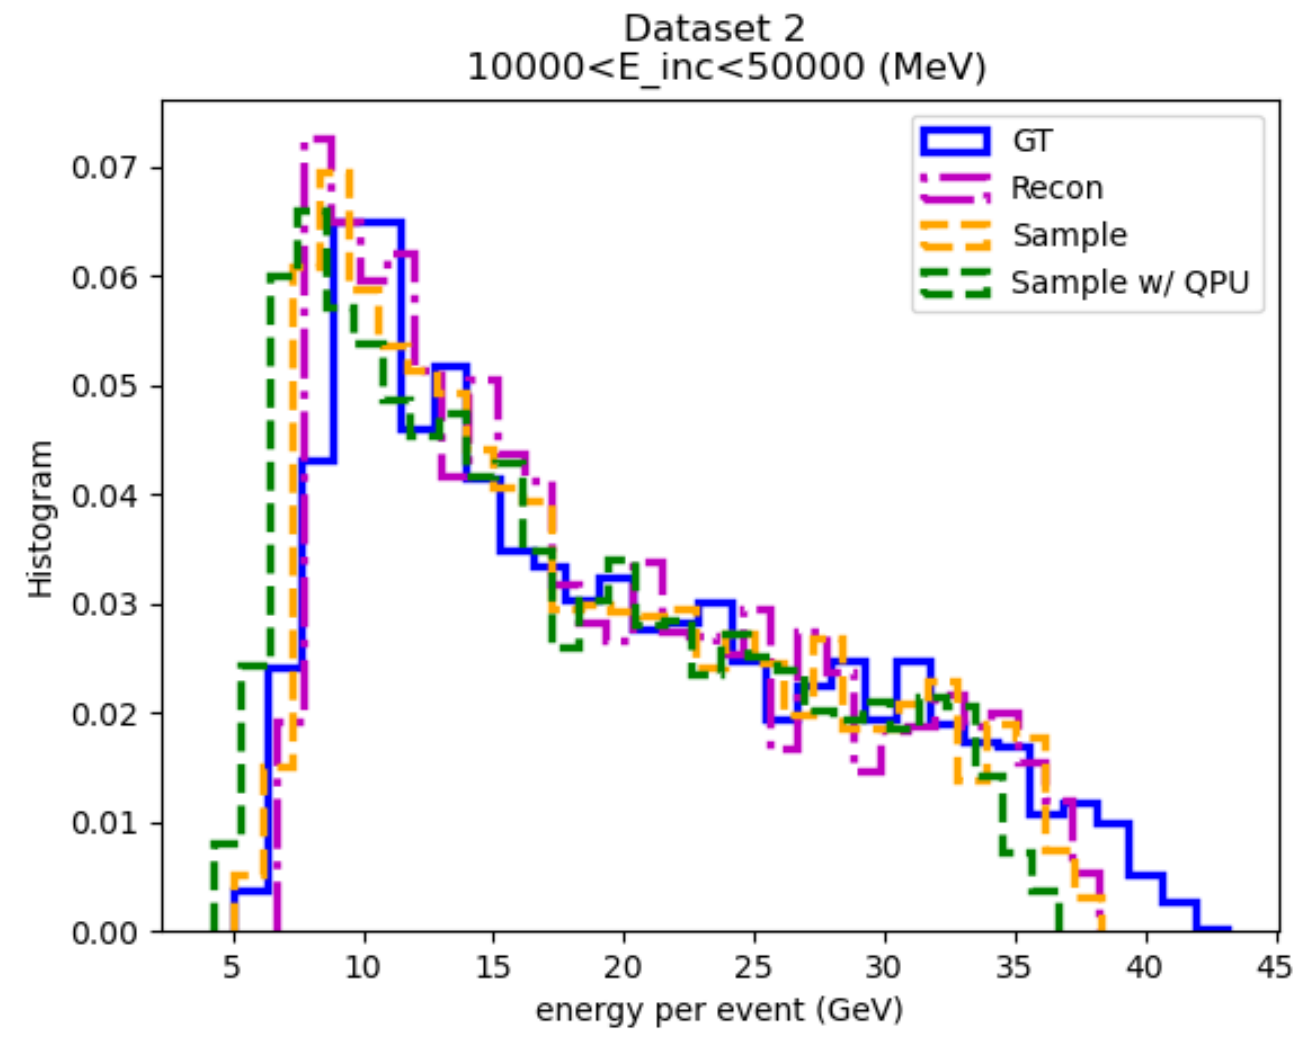

# Model comparison

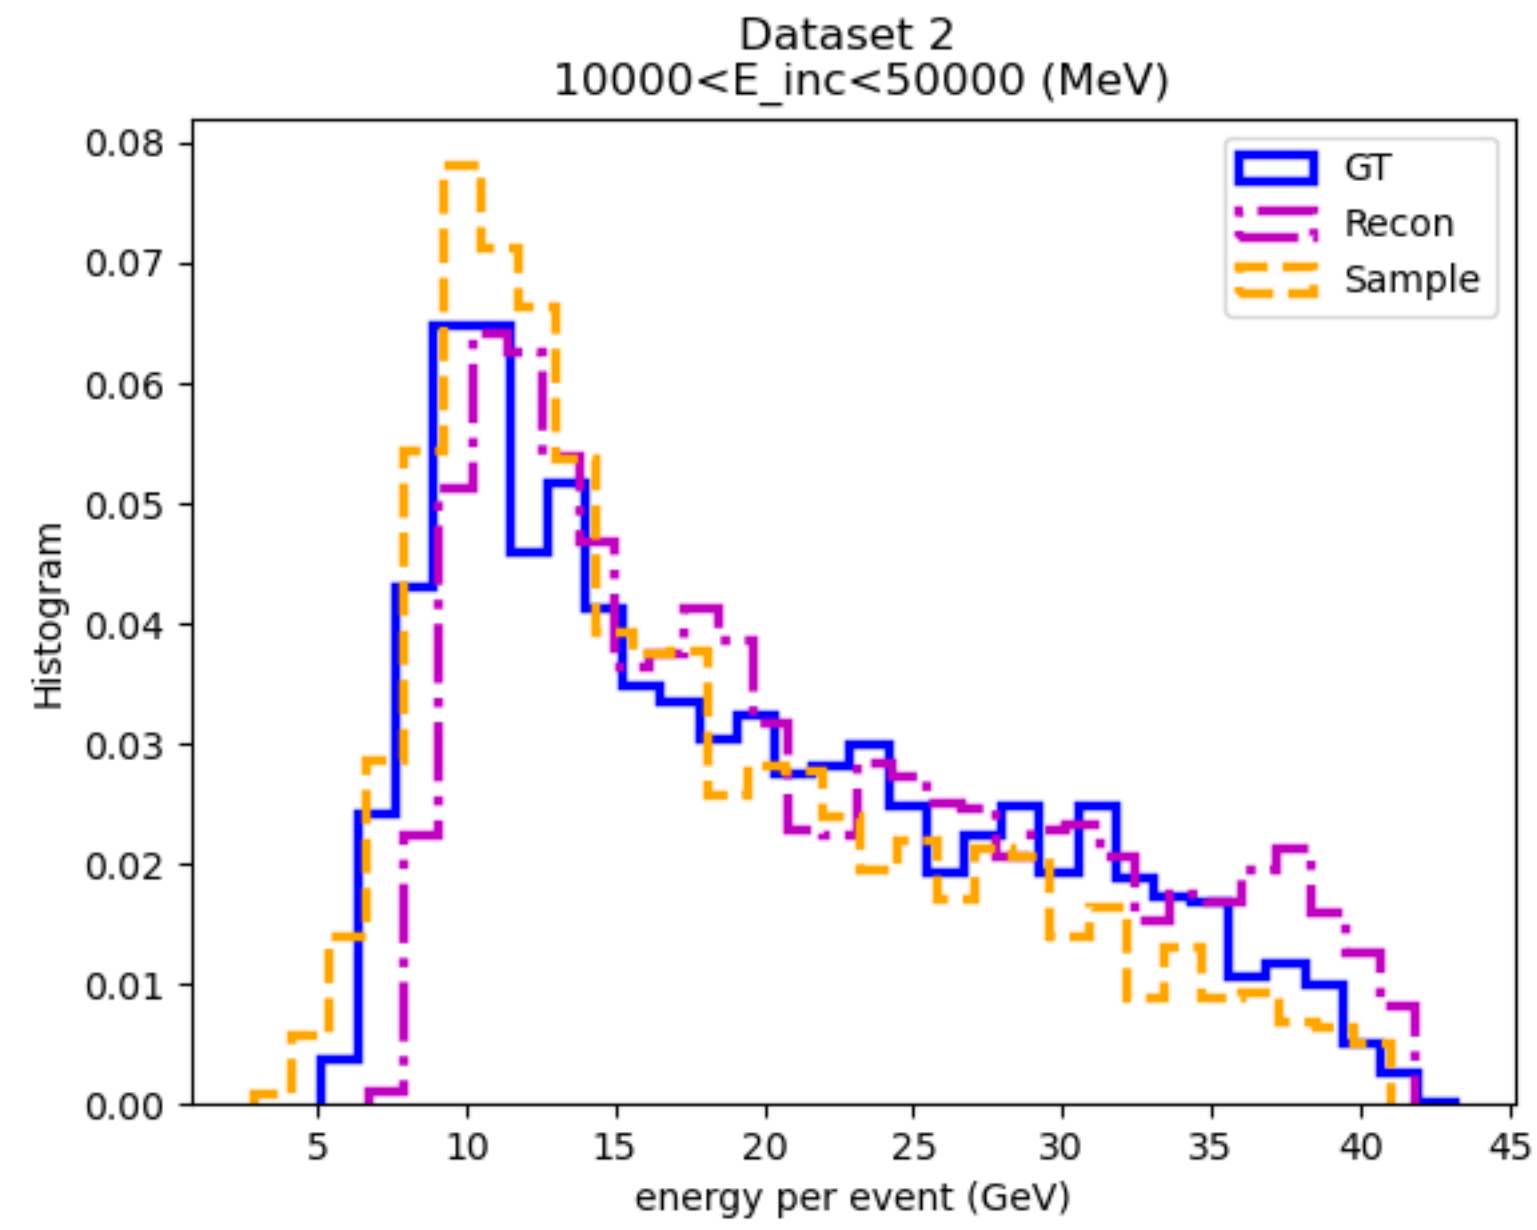

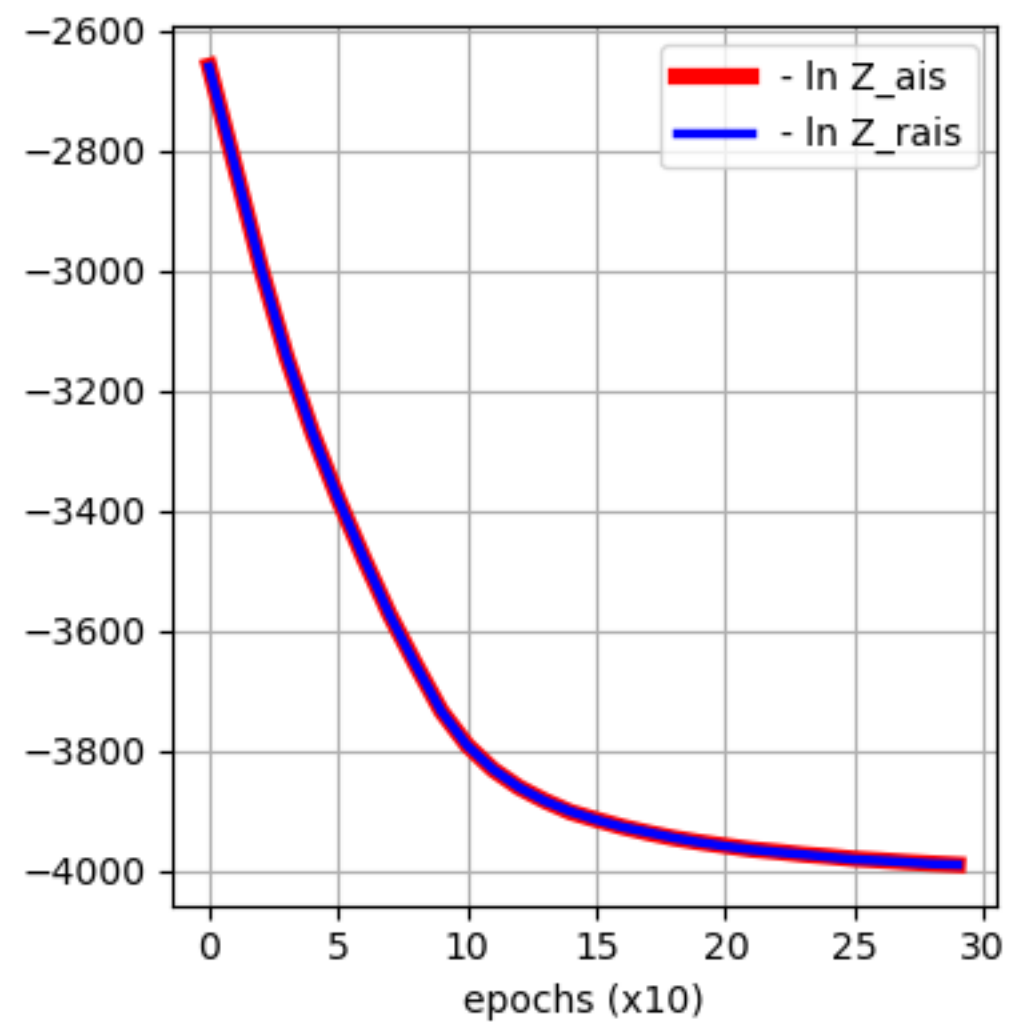

No weights on BLE

$$w(x) = 1 + x$$

$$w(x) = \sqrt{1 + x}$$

$$\ln \frac{x - \hat{x}}{x} \propto \frac{1}{2} \ln \frac{1}{x}$$

$$x - \hat{x} \propto \sqrt{x}$$
