Dark Matter and Dark Sectors at the LHC.

Diallo BOYE

Dark Interactions Workshop 2024 Simon Fraser University Harbour Centre (Vancouver)

[On behalf of the ATLAS and CMS Collaboration]

How do we know Dark Matter (DM) existence ?

• Galaxy Rotation Curves: stars at the outer edges rotate faster than expected \rightarrow presence of a large amount of unseen mass \Rightarrow DM.

How do we know Dark Matter (DM) existence ?

- Galaxy Rotation Curves: stars at the outer edges rotate faster than expected \rightarrow presence of a large amount of unseen mass \Rightarrow DM.
- Gravitational Lensing: bending of light from distant objects (gravitational lensing) stronger than what would be expected if only visible matter were present: $DM \Rightarrow$ provides the extra gravitational influence.

Diallo BOYE

How do we know Dark Matter (DM) existence ?

- Galaxy Rotation Curves: stars at the outer edges rotate faster than expected \rightarrow presence of a large amount of unseen mass \Rightarrow DM.
- Gravitational Lensing: bending of light from distant objects (gravitational lensing) stronger than what would be expected if only visible matter were present: $DM \Rightarrow$ provides the extra gravitational influence.
- Cosmic Microwave Background (CMB): precise measurements of the CMB $\Rightarrow 27\%$ of the universe is composed of DM, far exceeding the amount of normal (baryonic) matter.

Why would Dark Matter matter?

$\mathrm{DM} \rightarrow \mathrm{central}$ to Structure Formation

• In the early universe, dark matter acted as the gravitational scaffolding for the formation of galaxies and large-scale structures. Without dark matter, the universe would not have had enough gravitational clumping to form galaxies and galaxy clusters as quickly as we observe today.

Why would Dark Matter matter?

$\mathrm{DM} \rightarrow \mathrm{central}$ to Structure Formation

• In the early universe, dark matter acted as the gravitational scaffolding for the formation of galaxies and large-scale structures. Without dark matter, the universe would not have had enough gravitational clumping to form galaxies and galaxy clusters as quickly as we observe today.

Gaps in the Standard Model (SM)

- The SM of particle physics describes the known particles and forces very well, but it does not account for $DM \rightarrow$ there must be new physics beyond the SM that can explain DM.
- Discovering DM could help extend the SM, shedding light on new interactions or forces in nature.

Why would Dark Matter matter?

$DM \rightarrow central to Structure Formation$

• In the early universe, dark matter acted as the gravitational scaffolding for the formation of galaxies and large-scale structures. Without dark matter, the universe would not have had enough gravitational clumping to form galaxies and galaxy clusters as quickly as we observe today.

Gaps in the Standard Model (SM)

- The SM of particle physics describes the known particles and forces very well, but it does not account for $DM \rightarrow$ there must be new physics beyond the SM that can explain DM.
- Discovering DM could help extend the SM, shedding light on new interactions or forces in nature.

DM as a New Form of Matter

- If DM is made of WIMPs or other exotic particles, understanding it could revolutionize our knowledge of matter and the universe.
- This opens up the possibility of discovering dark sectors: hidden particles and forces that only weakly interact with the SM, introducing a whole new realm of physics.

How to search for Dark Matter?

Direct detection experiments

• Attempt to observe DM particles interacting with ordinary matter on Earth (e.g., through nuclear recoil in detectors)E.g Xenon 1T experiment.

How to search for Dark Matter?

Direct detection experiments

• Attempt to observe DM particles interacting with ordinary matter on Earth (e.g., through nuclear recoil in detectors)E.g Xenon 1T experiment.

Indirect detection

• Looks for the products of DM annihilations/decays in space, such as high-energy photons, neutrinos, or cosmic rays. E.g IceCube experiment ^{ISP}.

How to search for Dark Matter?

Direct detection experiments

• Attempt to observe DM particles interacting with ordinary matter on Earth (e.g., through nuclear recoil in detectors)E.g Xenon 1T experiment.

Indirect detection

• Looks for the products of DM annihilations/decays in space, such as high-energy photons, neutrinos, or cosmic rays. E.g IceCube experiment ^{ICP}.

Collider searches

- Involve producing DM in high-energy collisions, which would escape detection and show up as missing transverse energy (MET).
 - E.g LHC experiment \mathbb{R} .

Diallo BOYE

Collider Searches for Dark Matter

DM as WIMPS \rightarrow MET

- WIMPs as DM remains an attractive option which can be directly produced at the LHC.
- It would interact weakly then pass invisibly through detectors.
- Consequently, collider searches focus on production of a SM particle(s) (X) with E_T^{miss} from the hypothetical WIMP.
- Initial state radiation (photons, jets, vector bosons) or associated production can tag DM pair production.

Collider Searches for Dark Matter

DM as WIMPS \rightarrow MET

- WIMPs as DM remains an attractive option which can be directly produced at the LHC.
- It would interact weakly then pass invisibly through detectors.
- Consequently, collider searches focus on production of a SM particle(s) (X) with E_T^{miss} from the hypothetical WIMP.
- Initial state radiation (photons, jets, vector bosons) or associated production can tag DM pair production.

DM mediator - Dark sector

- As a complementary approach, Dark Sector concept is used for the detection of a DM mediator that talk between SM and a Dark sector which then decay back to SM particles.
- As an example, the Higgs boson could decay to a dark photon mediator that decays to leptons. This process is also known as the Higgs portal.

DM search at the LHC: outline

• MET-signature

- General MET search: monojet
- H to invisible (MET)

2 Dark sector

- Prompt DM mediator
- Long Lived Particle as DM mediator
- Semi-visible
- **③** Dark matter summary at the LHC
- Conclusion

Monojet analysis • PhysRevD.103.112006

At least a high energetic jet & large E_T^{miss} and no leptons
Different interpretations including DM simplified models.

7/32

Mono-jet interpretation PhysRevD.103.112006

• For $m_{Z_A} > 2 \times m_{\chi}$, mediator masses up to about 2.1 TeV are excluded for $m_{\chi} = 1$ GeV.

Mono-jet interpretation • PhysRevD.103.112006

- For $m_{Z_A} > 2 \times m_{\chi}$, mediator masses up to about 2.1 TeV are excluded for $m_{\chi} = 1$ GeV.
- m_Z below 376 GeV are excluded for very light WIMP.

Mono-jet interpretation • PhysRevD.103.112006

- For $m_{Z_A} > 2 \times m_{\chi}$, mediator masses up to about 2.1 TeV are excluded for $m_{\chi} = 1$ GeV.
- m_Z below 376 GeV are excluded for very light WIMP.
- The observed exclusion reaches up to $m_{med} = 1.95$ TeV (2.2 TeV expected) for $m_{DM} = 1$ GeV.

Mono-jet interpretation • PhysRevD.103.112006

- For $m_{Z_A} > 2 \times m_{\chi}$, mediator masses up to about 2.1 TeV are excluded for $m_{\chi} = 1$ GeV.
- m_Z below 376 GeV are excluded for very light WIMP.
- The observed exclusion reaches up to $m_{med} = 1.95$ TeV (2.2 TeV expected) for $m_{DM} = 1$ GeV.
- Similar observation for the vector mediator
- JHEP11(2021)153

Higgs to invisible search at the LHC

• Invisible Higgs carries off momentum, characterised by large missing transverse momentum in the events

- Four different channels for the Higgs to invisible search
- Very unlikely process in Standard Model; branching ratio $\mathcal{B}_{H \to inv} \sim 1.05 \times 10^{-3}$ from $H \to ZZ^* \to 4\nu$
- Can be significantly enhanced in various BSM scenarios, including Higgs coupling to dark matter ("Higgs portal").

Vector Boson Fusion: VBF

- Strong background rejection due to its distinct event topology.
- The most sensitive mode for invisible decays of a Higgs boson at hadron colliders
- Three mains backgrounds: Z strong, Z electroweak and di-boson production.

Event selection

- At least two jets with $p_T(j_1/j_2) > 80/50$ GeV.
- Jets in opposite hemispheres: $\Delta \eta_{jj} > 3.8$.
- $m_{jj} > 0.8$ TeV, Veto on e and μ

VBF Higgs \rightarrow inv interpretation (* JHEP 08 (2022) 104)

• Di-jets invariant mass (m_{jj}) showing a good agreement between data and expectation.

VBF Higgs \rightarrow inv interpretation • JHEP 08 (2022) 104

- Di-jets invariant mass (m_{jj}) showing a good agreement between data and expectation.
- Similar results from CMS.

VBF Higgs \rightarrow inv interpretation (* JHEP 08 (2022) 104)

- Di-jets invariant mass (m_{jj}) showing a good agreement between data and expectation.
- Similar results from CMS.
- Limit set on the wimp-necleon cross-section w.r.t m_{wimp}

VBF Higgs \rightarrow inv interpretation (* JHEP 08 (2022) 104)

- Di-jets invariant mass (m_{jj}) showing a good agreement between data and expectation.
- Similar results from CMS.
- Limit set on the wimp-necleon cross-section w.r.t m_{wimp}
- Limits set on the $\sigma_{\text{DM-nucleon}}$ vs m_{dm}
- Phys. Rev. D 105 (2022) 092007
- Complementary between collider and direct detection observed.

• Probing $BR(H \rightarrow Inv)$ at the 10% level! with Run1+Run2 combination.

- Probing $BR(H \rightarrow Inv)$ at the 10% level! with Run1+Run2 combination.
- CMS \rightarrow BR $(H \rightarrow$ Inv) < 0.15.

- Probing $BR(H \rightarrow Inv)$ at the 10% level! with Run1+Run2 combination.
- CMS \rightarrow BR $(H \rightarrow$ Inv) < 0.15.
- The combined Run 1+2 result is translated into upper limits on the WIMP-nucleon scattering cross-section for Higgs portal models.

• Probing $BR(H \rightarrow Inv)$ at the 10% level! with Run1+Run2 combination.

• CMS \rightarrow BR $(H \rightarrow$ Inv) < 0.15.

- The combined Run 1+2 result is translated into upper limits on the WIMP-nucleon scattering cross-section for Higgs portal models.
- Powerful constraint at low mass for collider search vs to direct one

 $(\bullet \text{ arXiv:}2303.01214)$

DM search at the LHC: outline

MET-signature

- General MET search: monojet
- H to invisible (MET)

O Dark sector

- Prompt DM mediator
- Long Lived Particle as DM mediator
- Semi-visible
- **③** Dark matter summary at the LHC
- Conclusion

Dark sector: Dark photon search

- HAHM (Hidden Abelian Higgs Model) → Curtin et al. (Phys.Rev.D90,075004(2014).), H. Davoudiasl et al Phys.Rev.D88.1(2013)015022
 - Predict a dark photon mediator Z_d that interacts with SM through kinetic mixing parameter ϵ .
 - Dark Higgs mechanism could spontaneously break the U(1) dark gauge symmetry (\rightarrow mixing between SM Higgs and dark Higgs \rightarrow mixing parameter κ)

- 2HDM+S Curtin et al. (Phys.Rev.D90, 075004(2014).), H. Davoudiasl et al Phys.Rev.D88.1(2013) 015022
 - It predicts the decay of the Higgs boson to 1 or 2 pseudo-scalar *a* determined by Yukawa couplings of *a* to fermions.

Diallo BOYE

LHC 14/32

Dark sector: Dark photon search: (Phys. Rev. D 90, 075004)

- Left: Branching ratios for Z_d decay, to lowest order and without QCD corrections, assuming decays to the dark sector are kinematically forbidden.
- Right: Branching ratios of a singlet-like pseudoscalar in the 2HDM+S for Type II Yukawa couplings.

Dark photon mediator in the Higgs portal • JHEP03(2022)041

• Different analyses:

•
$$H \to ZZ_d, Z_dZ_d, aa \to 4\ell.$$

- Mass range:
 - $Z_d \in [15-60]$ GeV.
 - $a \in [1-20]$ GeV
- Observable:
 - m_{34} for ZZ_d channel \rightarrow di-lepton mass most distant from the Z mass.
 - $\langle m_{\ell\ell} \rangle$ for $Z_d Z_d$ and $aa \to$ average di-lepton mass.

- No significant excess observed above the SM expectation.
- Results are interpreted in the HAHM and 2HDM+S models.
- Expected and Observed Limit is set at 95% CL on the branching ratio.

Dark photon mediator in the Higgs portal • JHEP03(2022)041

- The highest excess corresponds to a local significance of 2.5σ at m_{Z_d} = 28 GeV corresponding to $H \rightarrow Z_d Z_d \rightarrow 4\ell$ channel.
- This analysis is extended $S \rightarrow Z_d Z_d \rightarrow 4\ell$ where S is a scalar $m_S \neq m_{(H=125)}$.

Dark photon mediator in the Higgs portal • epic/s10052-022-10127

- CMS performed the same search.
- With no significant excess, limit was set on the Br and also on κ.
- A mediator decaying to di-muon is also performed in LHCb.
- Mass range below 1 GeV is probed, complementing ATLAS and CMS phase space.

• Note that the model probe in LHCb is a minimal vector portal model that doesn't require a Higgs portal.

Prompt Lepton Jets • EXOT-2018-55

Experimental signature

- 2 benchmarks models: HAHM and FRVZ
- Final states: Lepton Jet (LJ) \rightarrow collimated bundles of leptons.
- $m_{\gamma_d} \in [10 \text{ MeV} 10 \text{ GeV}].$
- 3 channels: 2eLJ, 2μ LJ and eLJ+ μ LJ

Analsysis strategy

- main bkg: Internal $\gamma *$, Z+jets and di-muon resonance.
- Triggers: single and di-electrons triggers for 2eLJ and di-muons trigger for 2µLJ.
- Bkg estimates: ABCD method for 2eLJ and Bump Hunting for 2µLJ.

Prompt Lepton jets • EXOT-2018-55

Results

- No significant excess in the data above the Standard Model background is observed.
- Left: 95% CL limits on BR(H $\rightarrow 2\gamma_d$) w.r.t m_{γ_d} using the HAHM model.
- Right: 95% CL limits on BR($\mathbf{H} \rightarrow 2\gamma_d + X$) w.r.t m_{γ_d} using the FRVZ model.
- Most stringent limits up to date probing for the first time γ_d mass down to ~ 10 MeV.

Unconventional signature: Long Lived Particles (LLP)

LLP is challenging

- Weak coupling to the SM leads to long-lived-particles (LLPs).
- challenges come from:
 - Decaying far from the primary vertex (PV), requiring special tracking.
 - Unusual shower shapes in calorimeters, unique fractions of ECal/HCal energy.
 - Need for timing information.
- The exclusion plot from the minimal vector portal dark-photon model shows an unexplored region of LLP of the dark photon.
- The very displaced area is accessible only via Higgs portal with ATLAS and CMS.

LLP decaying to a pairs of di-muons (**NEW-Run 3**)

Experimental signature

- 2μ from a secondary vertex spatially separated from the IP by distances ranging from hundred μm to several meters.
- New triggers for displaced di- μ developed for Run 3.

Results and interpretation

- Results interpreted in the framework of the HAHM, in which $H \rightarrow ZdZd$ where Z_d is a long-lived dark photons.
- Most stringent limit to date in wide regions of lifetimes for LLPs with masses larger than 10 GeV.

• R-parity violating SUSY model interpretation is also considered.

Displaced dark-photon jets • JHEP06(2023)153

- LL dark photons in the decay of a Higgs boson produced via gluon-gluon fusion or in association with a W boson.
- Select events with displaced collimated SM fermions from the calorimeter muon spectrometer.
- FRVZ model and HAHM model considered.

Diallo BOYE

LHC 23/32

Search for strongly-coupled DM - semi visible jets

- Analogue to the SM, Dark Sector contains new confining force (dark QCD) \rightarrow dark quarks \rightarrow dark showers.
- Predicting a resonance production of a leptophobic Z'boson which decays into a pair of dark quarks generating dark shower as shown in the Feynman diagram.

- Unstable dark hadrons $\xrightarrow{\text{promptly}}$ to SM quarks, while the stable dark hadrons are DM candidates (E_T^{miss}).
- Leading to two jets (decay products of the Z') in the final state.
- These jets contain quarks, gluons, and dark matter particles, and are therefore referred to as "semi-visible" jets.
- ATLAS and CMS performed such analyses presented in the next slides.

Strongly coupled dark matter search • JHEP06(2022)156

- Dijets transverse mass m_T used as discriminant.
- BDT to enhance the sensitivity.
- Look for new resonance as an excess in the m_T distribution.
- No structure in m_T compatible with the signal is observed.
