**11th International Workshop on Neutrino-Nucleus  
Scattering in the Few-GeV Region – NuInt 2017**

*The Fields Institute, University of Toronto, June 30<sup>th</sup> 2017*

- Motivation
- GARNET with ANNRI at J-PARC
- Data Analysis and Model Building
- Summary

- A common technique for low-energy (few MeV)  $\bar{\nu}_e$  detection: Exploit **delayed coincidence** of signals from **inverse beta decay** reaction products

- 1) **Prompt signal** (some ns): positron motion + annihilation
  - 2) **Delayed signal** (some 10s to 100s of  $\mu\text{s}$ ):  $\gamma$ -ray(s) from **neutron capture**
- Visibility of delayed (“marker”) signal depends on neutron catcher nucleus
  - **With respect to background rejection, you want a delayed signal that ...**
    - ... follows shortly after the prompt signal  $\rightarrow$  cross-section; concentration
    - ... has a strong signature (in face of a Cherenkov threshold)  $\rightarrow$  Q-value

- ✓ Gadolinium ( $^{157}\text{Gd}$ ) has largest thermal neutron capture cross-section among all stable nuclei due to resonance states in thermal energy region
- ✓ High Q-value of  $>7.9$  MeV
- ✓ Incorporation of gadolinium into common target materials demonstrated
- ✗ Excitation energy often released in multiple  $\gamma$ -rays (cascade)
  - ➔ Some  $\gamma$ -rays can escape detection / be below the Cherenkov threshold

Good modeling of the  $\gamma$ -ray spectrum from thermal  $\text{Gd}(n,\gamma)$  is important to make reliable neutron tagging efficiency predictions with MC studies!

Isotope	Thermal neutron capture cross-section [barn]	Q-value [MeV]	$N_\gamma$
$^{155}\text{Gd}$	61100	8.5	$\sim 3-4$
$^{157}\text{Gd}$	254000	7.9	$\sim 3-4$
$^1\text{H}$	0.333	2.2	1
$^{12}\text{C}$	0.004	4.9	$\sim 1-2$
$^{16}\text{O}$	0.189	4.1	$\sim 2-3$

Side note: Uncertainty for radiative thermal neutron capture x-sec on Gd is about 10%!

# Gadolinium in Neutrino Experiments

## Liquid / Solid Scintillator Detectors

- Gadolinium loading is used in unsegmented ton-scale liquid scintillator  $\bar{\nu}_e$  detectors

**Daya Bay, Double Chooz, RENO** ( $\rightarrow \theta_{13}$ )

- Gd mass fraction: 0.1% ( $\sim 1$  g per liter)
  - Segmented plastic scintillator detectors can put film with Gd-coating between bars
- PANDA** ( $\rightarrow$  reactor monitoring)

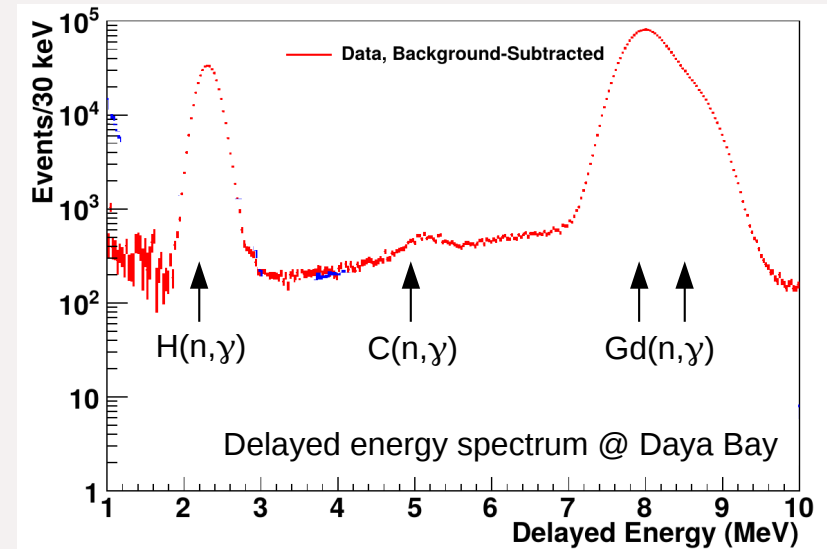

[PANDA module schematic; NIM A 757 (2014) 33-39]

- Calorimetric energy measurement
  - $\rightarrow$  Q-value of n-capture reaction observable if all  $\gamma$ -rays are fully contained
- Dedicated  $\gamma$ -catcher volume around target or fiducial volume cut!

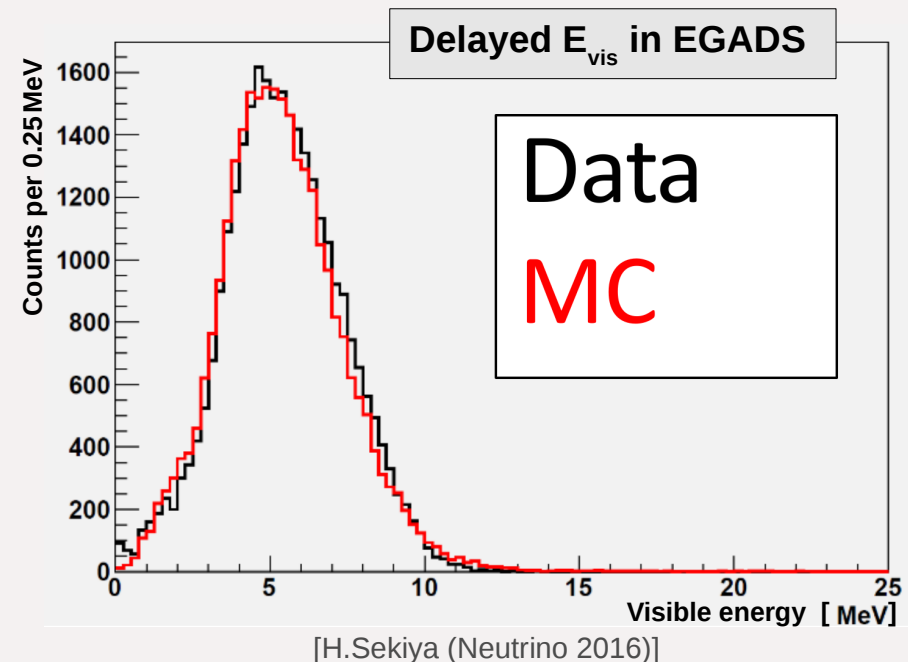

[Double Chooz schematic; Phys.Rev. D86 (2012) 052008]

[Chin.Phys. C41 (2017) no.1, 013002]

- Neutron tagging with 2.2 MeV  $\gamma$ -rays from  ${}^1\text{H}(n,\gamma)$  has low efficiency due to Cherenkov threshold  $\rightarrow$   $\gamma$ 's below  $\sim 1$  MeV produce no Cherenkov light!
- Gd-loading of water would advance this neutrino detector technology  $\rightarrow$  decrease energy threshold for  $\bar{\nu}_e \rightarrow$  e.g., improve SNR- $\nu$  flux search
- Sustainable Gd-loading of water was successfully demonstrated by **EGADS**
- **Super-K** will load 100t of  $\text{Gd}_2(\text{SO}_4)_3$  (0.2% concentration) in 2018!  $\rightarrow$  90% n-capture detection efficiency
- Due to Cherenkov threshold: mean visible energy is below the Q-value of  $\text{Gd}(n,\gamma)$
- A proper modeling of the energy distribution in the  $\text{Gd}(n,\gamma)$  cascade is important for MC-based efficiency studies!

- Gd will also be used for **neutron multiplicity measurements** in...
  - the ***E61 JPARC Intermediate Water Cherenkov Detector***

[Talk by *Marcus O'Flaherty* on Thursday]

- Project: **G**Amma-**R**ays produced in gadolinium **N**eutron capture **E**xperiment and  $\gamma$ -ray **T**ransition model
- Measured  $\gamma$ -ray spectra from Gd(n, $\gamma$ ) reaction with thermal neutrons
- Two data-takings with the **A**ccurate **N**eutron-**N**ucleus Reaction Measurement **I**nstrument (**ANNRI**) of the **M**aterials and **L**ife Science Experimental **F**acility (MLF) at J-PARC

➤ Neutron targets:

- **Natural Gd** film (99.99%), 5 mm x 5 mm x 10, 20  $\mu$ m
- **Enriched  $^{155}\text{Gd}$  (91.65%) /  $^{157}\text{Gd}$  (88.4%)** in  $\text{Gd}_2\text{O}_3$  powder

Composition of natural gadolinium

Isotope	Abundance ratio [%]	Thermal capture cross section [barn]
$^{152}\text{Gd}$	0.200	740
$^{154}\text{Gd}$	2.18	85.8
$^{155}\text{Gd}$	14.80	61100
$^{156}\text{Gd}$	20.47	1.81
$^{157}\text{Gd}$	15.65	254000
$^{158}\text{Gd}$	24.84	2.22
$^{160}\text{Gd}$	21.86	1.42

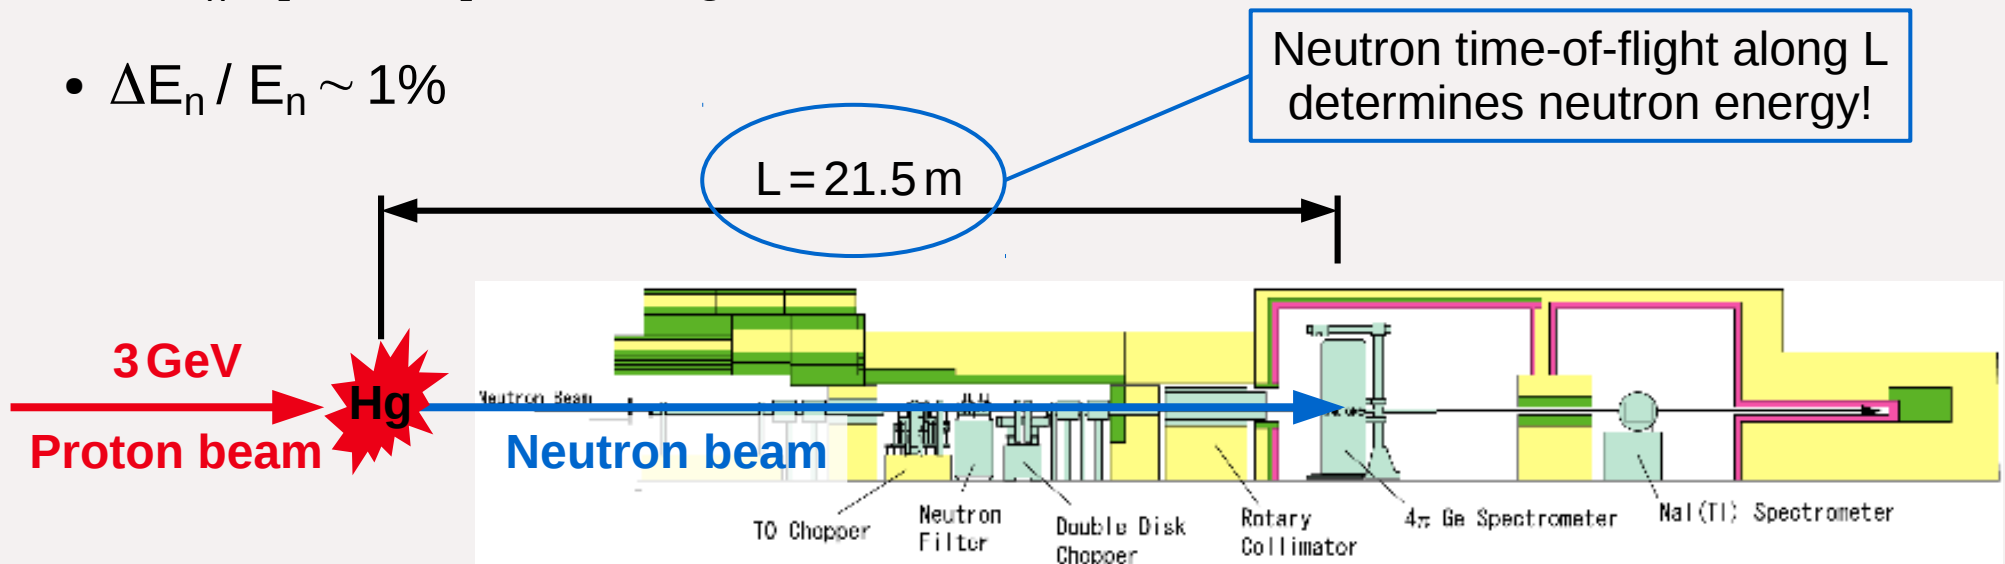

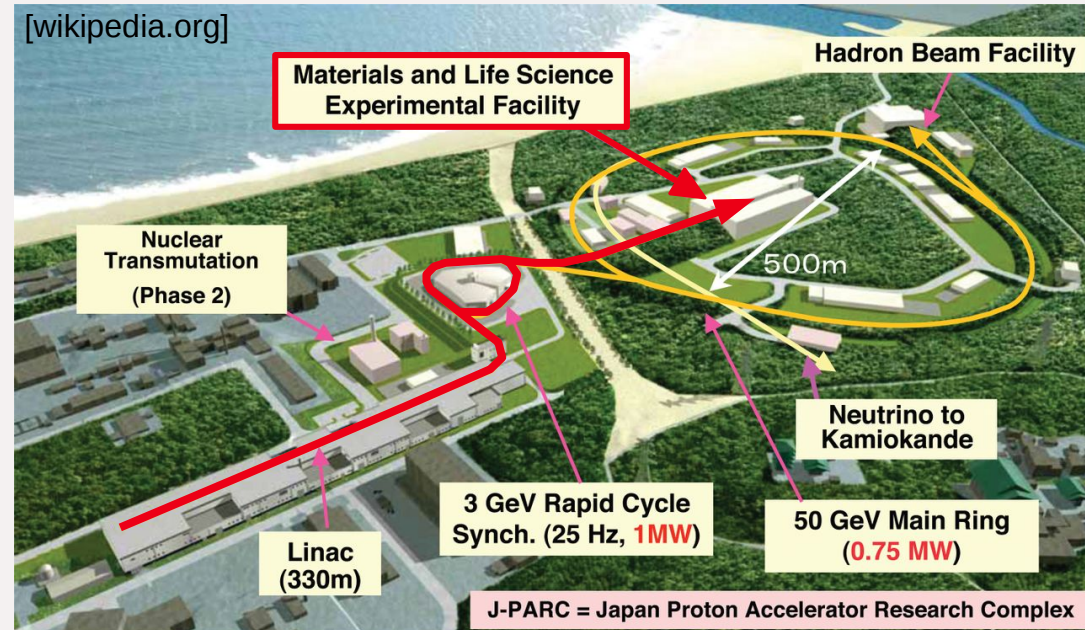

at 25 meV neutron energy

- Development of a Gd  $\gamma$ -ray cascade model for GEANT4 with GARNET detector simulation

- **First measurement of  $\gamma$ -ray spectrum from Gd(n, $\gamma$ ) in [0.1, Q-val] MeV with large statistics, small background (<1%) and excellent energy resolution**

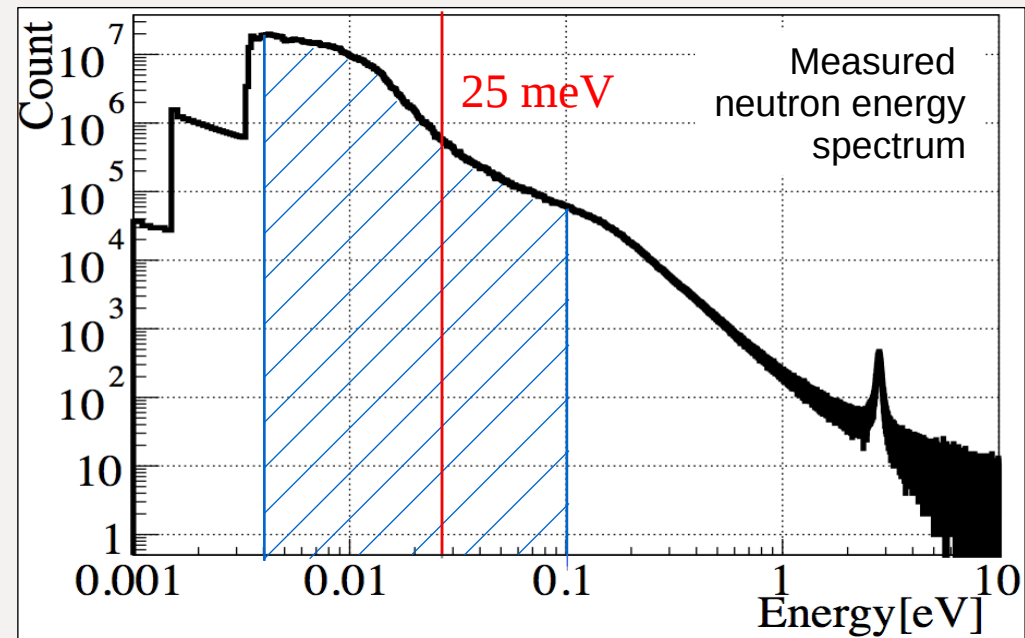

- ANNRI is located at beamline 04 of MLF
- Neutron source:
  - 3 GeV protons on Hg target
  - about 300 kW proton power
  - intensity at Gd target:  $1.3 \times 10^{11}$  n/(s $\cdot$ m $^2$ ) in  $E_n = [1.5, 25]$  meV range
  - $\Delta E_n / E_n \sim 1\%$

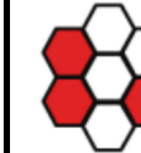

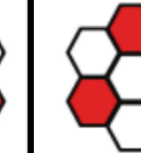

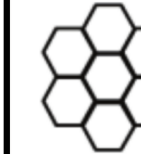

- **Used instrumentation:**
  - 2 Ge clusters (2 x 7 hexagonal crystals)
  - 2 BGO veto shields
- **Energy calibration / efficiency determination:**
  - Sources:  $^{22}\text{Na}$ ,  $^{60}\text{Co}$ ,  $^{137}\text{Cs}$ ,  $^{152}\text{Eu}$ ,
  - Targets:  $\text{NaCl}(n,\gamma)$ ; empty target holder for background measurement
- **Energy resolution of one Ge crystal:**  
~9.2 keV (FWHM) @ 1.3 MeV
- **Full-energy peak efficiency:**  
2.2% @ 1.3 MeV  
 (all 14 Ge crystals combined)
- **Solid angle coverage:**
  - 2 Ge clusters: 22%
  - 2 BGO vetoes: 55%

- **Event selection:**  
Only events in the thermal neutron energy range 4-100 meV
- **$\gamma$ -ray multiplicity M:**
  - Number of disconnected crystal sub-clusters over both Ge clusters
  - $M \leq$  true  $\gamma$ -ray multiplicity due to
    - ➔ limited solid angle coverage
    - ➔ Compton scattering over multiple crystals
- **Hit count H:** number of hit crystals
- **Reconstructed  $\gamma$ -ray energy:**  
Amount of deposited energy in sub-cluster

M	1	2	2	6 (MAX)
Up				
Down				
H	3	3	3	6

- Large event samples; more than  $3 \times 10^9$  events per Gd target

Target	Time	Number of Events	Source	Time	Number of Events
Nat. Gd	116 hours	$3.5 \times 10^9$	$^{22}\text{Na}$	5 minutes	$1.5 \times 10^7$
$^{155}\text{Gd}_2\text{O}_3$	38 hours	$3.1 \times 10^9$	$^{60}\text{Co}$	18 hours	$8.8 \times 10^7$
$^{157}\text{Gd}_2\text{O}_3$	55 hours	$4.6 \times 10^9$	$^{137}\text{Cs}$	30 minutes	$2.1 \times 10^6$
NaCl	4 hours	$1.3 \times 10^8$	$^{152}\text{Eu}$	7 hours	$2.3 \times 10^7$
Empty	6 hours	$1.3 \times 10^7$			

- Sub-samples for different  $\gamma$ -ray multiplicities
- For MC model building: describe spectrum by two parts
  - **Discrete peaks**
  - **Continuum**
 = same approach GLG4sim<sup>1</sup> uses for GEANT4 simulations

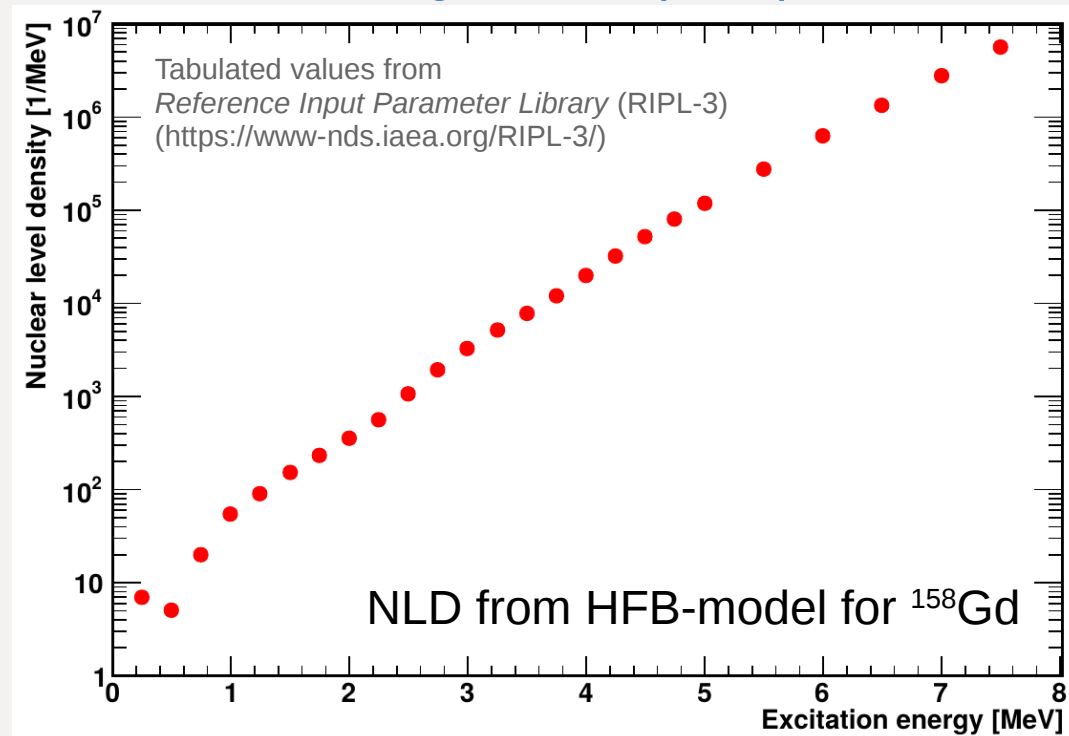

**In the following: only  $^{157}\text{Gd}(n,\gamma)$**

<sup>1</sup> Generic Liquid-scintillator Anti-Neutrino Detector Geant4 simulation  
<http://neutrino.phys.ksu.edu/~GLG4sim/> - last updated 2005

- Gadolinium ( $Z=64$ ;  $A \sim 152-160$  for nat. Gd) has a complex nuclear level structure
- *Nuclear Level Density* (NLD)  $\rho(E)$  increases with rising excitation energy  
**Discrete nuclear levels**  $\longrightarrow$  **a quasi-continuum of nuclear levels**
- Example  $^{158}\text{Gd}$ : NNDC<sup>1</sup> lists about 220 discrete levels up to  $\sim 4$  MeV, but there are many more!
- We use tabulated values of  $\rho(E)$  from the **Hartree-Fock-Bugoliubov (HFB) model**<sup>2</sup>

### Gadolinium Nuclear Level Structure

<sup>1</sup> National Nuclear Data Center (<https://www.nndc.bnl.gov/>)

<sup>2</sup> E.g., see Capote et al.: Nuclear Data Sheets 110 (2009) 3107–3214

- Discrete peaks are fixed, prominent transitions between nuclear levels
- We identified 15 discrete peaks in our data (prompt  $\gamma$ -ray energies from 7937 to 5167 keV)
- They are directly included into our model (GLG4sim uses 6 peaks)
- Their strengths are tuned to match our data
- For  $E > 110$  keV, they contribute  $(6.8 \pm 0.1)\%$  to our data

### Gadolinium disexcitation Discrete Peaks

- Our relative intensities of prompt  $\gamma$ -rays agree with *CapGam*<sup>1</sup> values within about  $\pm 30\%$

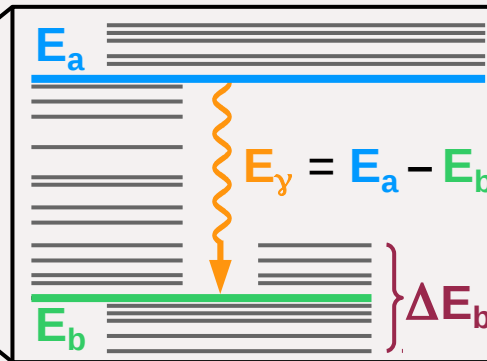

<sup>1</sup> Thermal Neutron Capture  $\gamma$ 's from NNDC (<http://www.nndc.bnl.gov/capgam/>)

- Continuum spectrum stems from (numerous) random transitions – especially within the high NLD domain;
- It contributes  $(93.2 \pm 0.1)\%$  to our data ( $E > 110\text{keV}$ )

### Gadolinium disexcitation Continuum

- We use a statistical model to calculate the transition probability  $P$  from  $E_a$  to  $E_b$  based on

- the NLD  $\rho(E)$ ,
- the *Photon Strength Function (PSF)  $f(E_\gamma, T)$* :

$$P(E_a, E_b) = \frac{dP}{dE}(E_a, E_b) \Delta E_b = \frac{T(E_\gamma) \rho(E_b) \Delta E_b}{\int_0^{E_a} T(E_\gamma) \rho(E_b) dE_b}, \quad T(E_\gamma) = 2\pi E_\gamma^3 f(E_\gamma, T)$$

Transmission coeff. for E1 transition

- Only E1 transitions considered

$$P(E_a, E_b) = \frac{dP}{dE}(E_a, E_b) \Delta E_b = \frac{T(E_\gamma)\rho(E_b)\Delta E_b}{\int_0^{E_a} T(E_\gamma)\rho(E_b)dE_b}, \quad T(E_\gamma) = 2\pi E_\gamma^3 f(E_\gamma, T)$$

Transmission coeff. for E1 transition

- For the **PSF** of the E1 transitions we use the **Enhanced Generalized Lorentzian (EGLO)** model<sup>1</sup> for a deformed nucleus

$$f(E_\gamma, T) = \sum_{i=1}^2 \left[ \frac{E_\gamma \Gamma_i(E_\gamma, T)}{(E_\gamma^2 - E_i^2)^2 + E_\gamma^2 \Gamma_i^2(E_\gamma, T)} + 0.7 \frac{\Gamma_i(E_\gamma = 0, T)}{E_i^3} \right] \sigma_i \Gamma_i$$

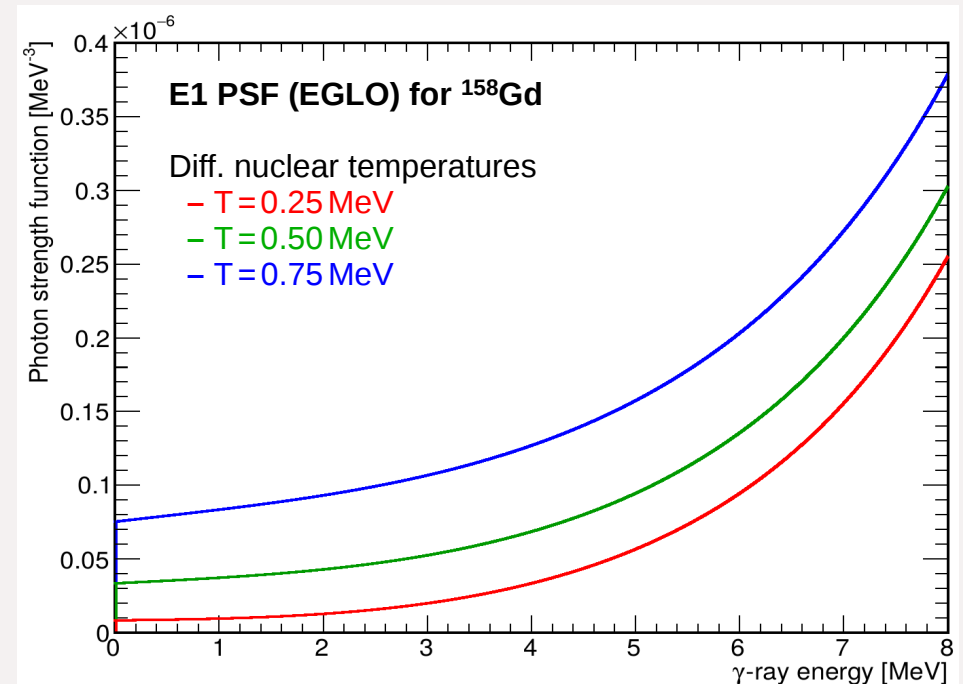

with

$$\Gamma_i(E_\gamma, T) = \left[ k_0 + \frac{E_\gamma - \varepsilon_0^\gamma}{E_i - \varepsilon_0^\gamma} (1 - k_0) \right] \frac{\Gamma_i}{E_i^2} (E_\gamma^2 + 4\pi^2 T^2)$$

and the E1 resonance parameters

	Energy ( $E_i$ ) [MeV]	Strength ( $\sigma_i$ ) [mb]	Width ( $\Gamma_i$ ) [MeV]
$^{158}\text{Gd}$	11.7	165	2.6
	14.9	249	3.8

[From RIPL-2; see also Phys. Rev. C 47, 312]

<sup>1</sup> E.g., see Capote et al.: Nuclear Data Sheets 110 (2009) 3107–3214

- Compare full model to data (continuum + discrete peaks)
- For single- $\gamma$ -ray events (M1H1): agreement within about  $\pm 50\%$  at  $\Delta E = 500$  keV
- Our model shows a better performance than the GLG4sim model
- Analysis is ongoing!
- Use different models for NLD / PSF

- We also compare the fractions of the different event classes ( $\gamma$ -ray multiplicities) in data and MC
- For the considered event classes, the agreement between data and MC is well within  $\pm 15\%$

- Gadolinium is a popular additive in neutrino detectors to enhance the delayed neutron capture signal of an IBD event
- Precise knowledge of the  $\gamma$ -ray spectrum from  $\text{Gd}(n,\gamma)$  is important to assess neutron tagging efficiencies with MC simulations
- We precisely measured the  $\gamma$ -ray spectra from thermal  $^{\text{Nat},155,157}\text{Gd}(n,\gamma)$  reactions with the ANNRI germanium spectrometer at J-PARC
- Based on the data, we build a model for the spectrum to generate the  $\gamma$ -rays in a MC simulation (GEANT4); 15 discrete peaks for  $^{157}\text{Gd}(n,\gamma)$  included and tuned to data; continuum part bases on statistical modeling
- Spectrum model and data currently agree within about  $\pm 50\%$  ( $\Delta E = 500 \text{ keV}$ ) for single- $\gamma$ -ray events; our model reproduces the different  $\gamma$ -ray multiplicities with below 15% deviation from our data

- Gadolinium is a popular additive in neutrino detectors to enhance the delayed neutron capture signal of an IBD event

**Thank you very much for your kind attention!**

# Further Information

FURTHER INFORMATION

➤ Trigger conditions:

- 1) At least one Ge crystal has  $E > 0.1$  MeV
- 2) The surrounding BGO has  $E < 0.1$  MeV

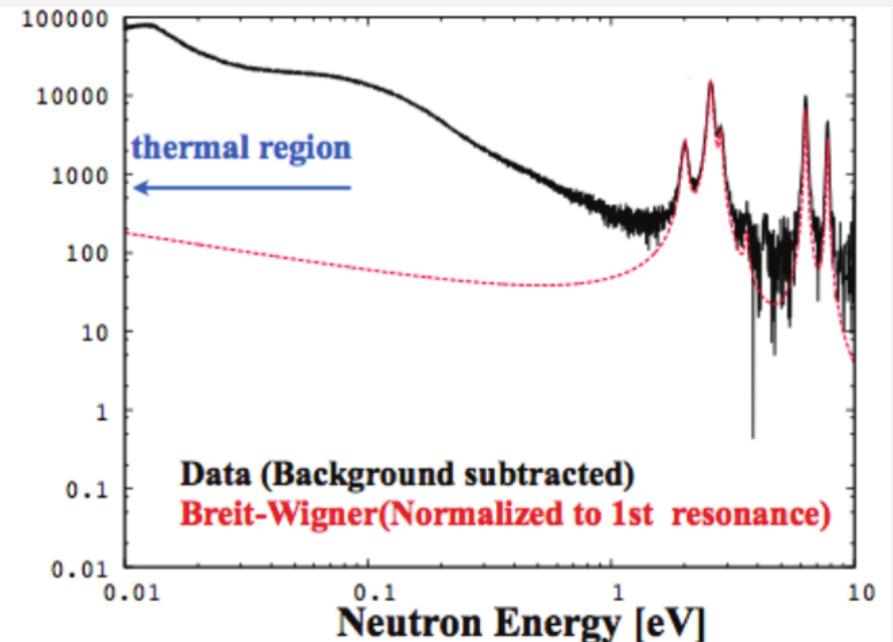

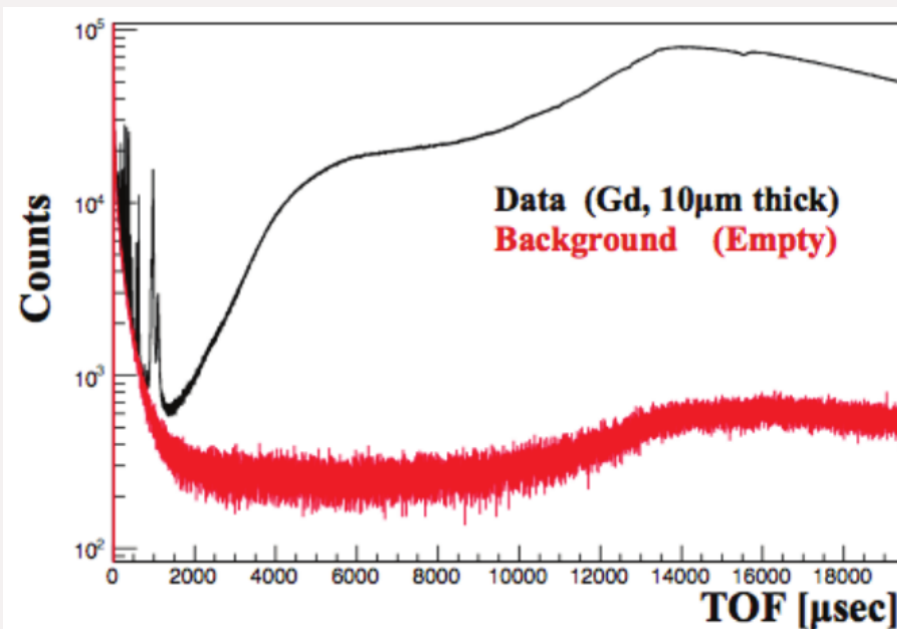

→ upper and lower cluster independent!

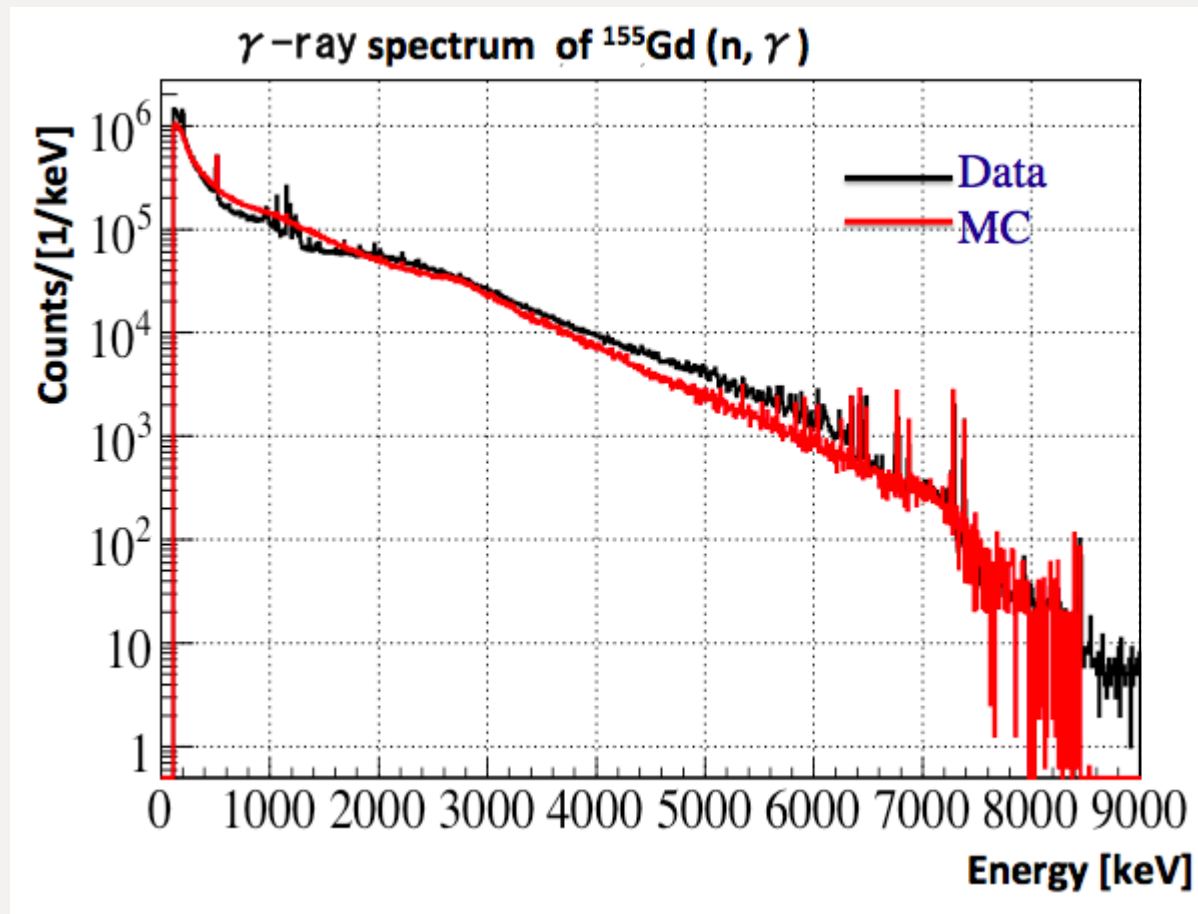

- With known distance ( $L=21.5$  m) between n-source and detector one can calculate the energy  $E_n$  of the thermal neutron with mass  $m_n$  from its time of flight  $T$  for the distance  $L$  with the classical formula

$$E_n = m_n (L/T)^2 / 2$$

- Resonances of  $^{155}\text{Gd}$  and  $^{157}\text{Gd}$  in detected neutron energy spectrum between 1 and 10 eV
  - ✓ Good agreement with calculated expectations
  - ✓ Reasonable isotope abundances in nat. Gd and good energy calibration

- Comparison of full model to data for  $^{155}\text{Gd}(n,\gamma)$

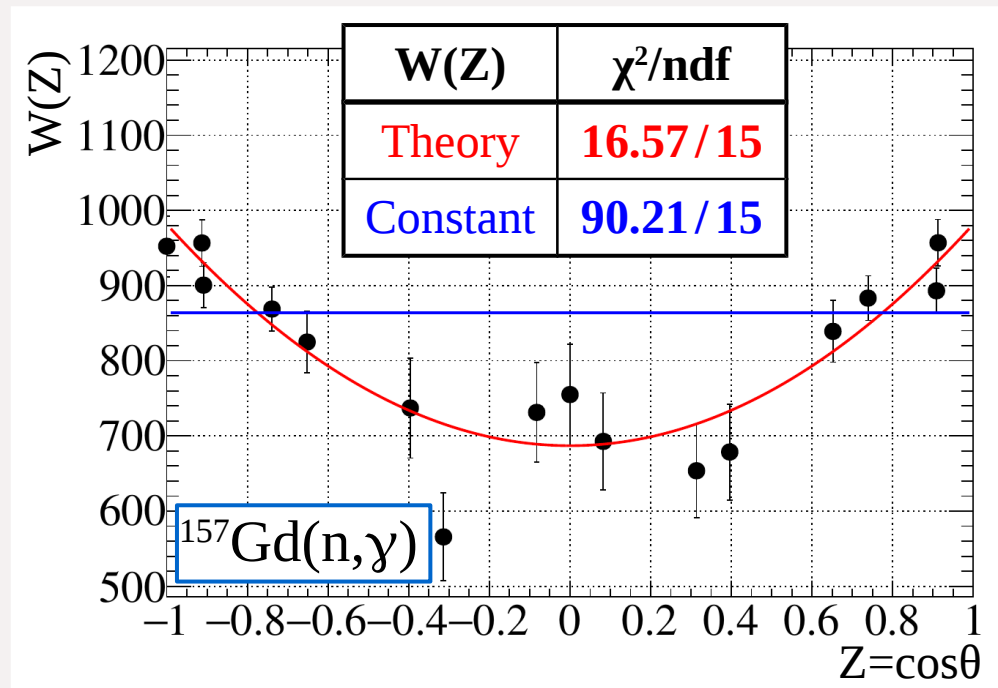

- We see the angular correlation of  $\gamma$ -rays from  $^{157}\text{Gd}(n,\gamma)$
- For the shown  $\gamma$ -ray lines it agrees with the theory<sup>1</sup>

$$W(Z) = A \left( 1 + \frac{3}{7} Z^2 \right)$$

for dipole-quadrupole transitions.

- Future: Study angular correlations with 8 additional co-axial counters.
